By-law 22.—An ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member; but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if:—

(a) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.

(b) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(c) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the By-laws.

(d) The nomination form is not received before or upon the day appointed therefor.

(e) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. LONGSTAFF,
General Secretary

Members Elected April 8, 1927

- Baker, Reginald, 71, First Avenue, Manor Park, London, E.12. Pupil Gas Engineer.
 Buning, Dr. Harm L., Bensine-Installatie K.N.P.M., Postbus 644, Rotterdam. Assistant Manager.
 Burman, Axel S., K. Patentverket, Valhallavägen, 136, Stockholm. Byrådirektor.
 Challenger, Dr. Frederick, Chemistry Dept., The University, Manchester. Lecturer.
 Daish, Arthur J., The Gas Works, Monkbridge, York. Chemist.
 Ewing, Homer H., 54, New Broad Street, London, E.C.2. Chemical Engineer.
 Hochstadter, Irving, 227, Front Street, New York City, N.Y., U.S.A. Chemical Engineer.
 Hyde, A. T., c/o Messrs. Walter Baker & Co., Ltd., Dorchester, Mass., U.S.A.
 Laing, John B., Railway Hotel, Haddington, N.B. Brewery Chemist.
 Myers, T. Henry, The Croft, Stainton Road, Marton, Yorks. Fuel Chemist.
 Nicholls, Frederick, Redheugh Gasworks, Gateshead-on-Tyne. Chemist.
 Pieper, Ernest J., Armstrong Cork & Insulation Co., Argo Laboratory, Gloucester, N.J., U.S.A. Chemist.
 Preston, Richard St. J., Riverside, Kinlochleven, Argyll. Physical and Electro Chemist.
 Schwartz, Andrew K., South Texas Cotton Oil Co., Houston, Texas, U.S.A. Chemical Engineer.
 Shortt, Arthur, St. Andrews, Clayton Road, Newcastle-on-Tyne. Industrial Chemist.
 Speakman, John B., Dept. of Textile Industries, The University, Leeds. Lecturer.
 Wigg, Edward W., 14, Woodland Road, Chelmsford, Essex. Engineer.

EDINBURGH AND EAST OF SCOTLAND SECTION

The Honorary Secretary, in his report, states that during the session six ordinary meetings were held jointly with the Local Section of the Institute of Chemistry. Papers were read by the President of the Society, Mr. F. H. Carr, C.B.E., on "Vitamins in their relation to industry"; by Mr. A. M. Cameron, B.Sc., on "Fire risks in industry"; by Dr. C. H. Lander on "The importance of fuel research in the coal problem"; by Mr. B. D. W. Luff on "The use of the microscope in qualitative analysis"; by Mr. J. Adam Watson on "Some chemical aspects of geology"; and by Mr. W. A. Williams on "Costs in industry." The meetings had been well attended, the average number being 50, the two Societies contributing towards the attendance.

The joint Scottish meeting arranged to take place in St. Andrews at the end of May last year had to be indefinitely postponed owing to the general strike. In view of the fact that the annual meeting is to be held in Edinburgh in July next, it was decided not to arrange a joint Scottish meeting this session, but it is hoped that such a meeting will take place next year.

Through the courtesy of Messrs. Scottish Oils, Ltd., an interesting afternoon was spent in a visit to the Grange-mouth Oil Refinery on April 20 last.

As there appeared to be very little desire on the part of members for the social evening which it was proposed

to hold in November, the committee decided to give up the project.

The total membership for 1926 was 148: 4 were transferred to other sections, 9 resigned, and there were 2 deaths, leaving 133, to which should be added 5 transferred from other sections and 4 new members, making a total membership of 142. The section had lost two members through death—Mr. P. J. Anderson, Librarian to the University of Aberdeen, and Mr. Allin Cottrell. Mr. Cottrell was a member of Committee, and was ever ready and willing to give his able services to promote the welfare of the Section and the Society as a whole.

The number of associates on the register was less than last year owing to several obtaining appointments outside the area of the section. A small sub-committee had been formed to keep in touch with associates and to bring the activities of the section before the notice of students in Edinburgh.

Mr. W. A. Williams, who has been chairman of the section for the last two years, retires from the chairmanship at the end of the present session. The section owes a great deal to Mr. Williams for his unfailing interest in its welfare and for his able participation in all its activities.

CALENDAR OF FORTHCOMING EVENTS

Apr. 21. INSTITUTION OF MINING AND METALLURGY, Burlington House, Piccadilly, W.1. Annual Meeting.

Apr. 22 FARADAY SOCIETY. *Oxford Meeting*. University and 23. Museum, Oxford. General discussion on "The theory of strong electrolytes." On April 22, from 3.30 to 5.0 p.m., and 5.45 to 7.15 p.m., Part I. "Mobilities of ions," will be given, including the following papers:—(1) Introductory paper. Report on conductivity of strong electrolytes in dilute solutions, by P. Debye. Communicated by E. Hückel. (2) Report on a revision of the conductivity theory, by L. Onsager. (3) Refractometric evidence for the existence of undissociated molecules and complex ions in solutions of strong electrolytes, by K. Fajans. (4) Electrolytic transference of water, true transference numbers, ionic mobilities and water sheaths of the ions, by H. Remy. (5) Ionic mobilities in non-aqueous solvents, by H. Ulich. (6) The mobilities of the elementary ions in methyl alcohol, by H. Hartley and H. R. Raikes. (7) Notes on the Debye-Hückel theory, by H. Hartley and R. P. Bell. (8) The ionisation of some typical strong electrolytes, by D. A. MacInnes. (9) A thermodynamical study of the system lead chloride-potassium chloride-water at 25° C., by A. J. Allmand and L. J. Burrage. (10) Note on the occurrence of points of inflexion in the concentration-vapour pressure curve of aqueous solutions of certain electrolytes, by A. J. Allmand. On April 23, from 9.30 to 11 a.m., and 11.30 to 1 p.m., and 2.15 to 3.45 p.m., Part II.—"Activity," will be held when the following papers will be given:—(1) Introductory paper. On the activity of electrolysis, by J. N. Brønsted. (2) Strong electrolytes in relation to statistical theory, in particular the phase integrals of Gibbs, by R. H. Fowler. (3) Note on the theory of Debye and Hückel, by D. L. Chapman. (4) Anomalies in the theory of solutions of strong electrolytes, by N. Bjerrum. (5) Mixed solutions of electrolytes and non-electrolytes, by G. Scatchard. (6) On the

thermodynamic properties of a few concentrated salt solutions, by H. S. Harned. (7) The activity of zinc chloride in concentrated solution, by F. Foxton and W. J. Shutt. (8) Influence of salts on solubility in non-aqueous solvents, by C. A. Kraus. (9) The use of amalgam electrodes for determining activities in methyl alcohol, by J. H. Wolfenden, C. P. Wright, N. L. Ross-Kane, and P. S. Buckley. (10) The significance of the activity coefficient, by Merle Randall. (11) Methods of calculation of activity coefficient, by Merle Randall. (12) Electrochemical properties of non-aqueous solution of strong electrolytes, by J. R. Partington. (13) The definition and characteristics of strong electrolytes, by T. M. Lowry. (14) The activity of hydrogen ion in mixed solvents as a function of environment, by H. Millet.

Apr. 25. INSTITUTION OF MECHANICAL ENGINEERS. *Graduates' Section*, London. Storey's Gate, St. James's Park, S.W.1, at 7 p.m. "Parcel and package conveying plant," by H. W. Cadman.

Apr. 25. SOCIETY OF CHEMICAL INDUSTRY. *Chemical Engineering Group*. Additional Meeting at the American Film Co., Ltd., 89-91, Wardour Street, London, W.1, at 8 p.m. "Permanent moulding machines for cast iron," by Prof. J. W. Hinchley, illustrated by a film showing the process. Informal Dinner at 6.30 p.m., at the Restaurant Au Petit Riche, 44, Old Compton Street, W.1.

INSTITUTION OF MINING AND METALLURGY

The annual dinner of the Institution of Mining and Metallurgy was held on April 6 in the Hotel Victoria, Sir Thomas H. Holland presiding. The chief guest was Mr. Amery, Secretary of State for Dominion Affairs and the Colonies, who proposed the toast of "The Mineral and Metal Industries of the Empire." He said that the whole fabric of civilisation had grown up in the main on the two great pillars of agriculture and metallurgy. Nothing had been a more dominant factor than the utilisation of metals, both for the conquest of man over nature, and over his fellow man. It was possible that the great new discoveries of gold might have a very stimulating effect in bringing about the recovery of the world from the depression which followed the Great War. We were under the obligation of paying to the United States 6,700 tons of gold, which we should probably have to pay in work, in British goods, and service spent to acquire the gold to be paid back. The problem of the American debt was, therefore, much more one for the prospector and the mining engineer than for the financier. Sir Robert Horne, M.P., president of the Empire Mining and Metallurgical Congress in Canada this year, replied. He said that judging from the response which was coming from the various Dominions and Colonies, he had the greatest hope of a meeting in Montreal in August such as had rarely been seen in the history of the world, and he believed that they would be able to do something which would be of the greatest possible value. He hoped that they would all do their utmost to encourage the investigations which were being made at the present time for the better use of coal. If a method could be discovered by which all the constituents of coal could be most usefully employed, it would enormously add to the wealth of

this country. No investigation was of any use unless they could show that the result of the expenditure upon it would yield a revenue upon the capital invested.

The toast of "Our Guests," proposed by Dr. William Cullen, was responded to by Sir Alfred Mond, M.P., who said he agreed that the world required a new gold inflation. The prosperity of the world had always been in ratio to the discovery of new goldfields. Limitations of trade went together with limitations of credit. People wondered at the prosperity of America. How much of that prosperity was due to the fact that by a most ingenious elaboration dead credits had been mobilised and harnessed to the wheels of industry? That enabled them to produce a condition of prosperity which was likely to remain a leading factor. We wanted new methods in industry and new methods in finance. Unless some of our industries destroyed antiquated and obsolete machinery, and introduced more advanced methods of research, they could not expect to survive the modern competition of Germany and America. Speaking of the great chemical merger with which he was associated, he said that this had been made because it was realised that if the chemical industry was to survive in the front rank, as they intended it should, it could only be done by the pooling of brains, finance, technical knowledge, and research. In a few months they were obtaining results from the merger which he did not think would have been obtained in years. Lord Meston proposed the health of "The President of the Institution," which the chairman acknowledged.

PERSONAL AND OTHER ITEMS

Dr. W. E. Garner has been appointed to succeed Prof. J. W. McBain as professor of physical chemistry in the University of Bristol.

Dr. M. W. Travers has been appointed reader in applied physical chemistry and an honorary professor in the University of Bristol.

The degree of D.Sc. of London University has been conferred upon Mr. W. H. J. Vernon for a thesis entitled "The Atmospheric Corrosion of Metals (Second Experimental Report to the Atmospheric Corrosion Research Committee)."

Prof. H. Freundlich has been appointed deputy director of the Kaiser Wilhelm Institute for physical and electro-chemistry.

The trustees of the John Simon Guggenheim Memorial Foundation have announced the awards of fellowships for 1927-28 to, *inter alios*, Dr. R. B. Harvey, for research into low-temperature effects on plants, principally at Cambridge (Dr. Harvey has discovered that ethylene will hasten the ripening of fruit and vegetables), Dr. L. V. Heilbrunn, for research into the colloid chemistry of protoplasm, and to Dr. J. W. Woodrow, for research on the phosphorescent, chemi-luminescent, and photo-electric properties of cod liver oil and other substances which either have anti-rachitic properties or can be activated by ultra-violet irradiation, principally with Prof. Sir E. Rutherford at Cambridge and Prof. J. E. S. Townsend at Oxford.

Mr. John Parke Jackson, who has been connected with the Salt Union for 27 years, has been appointed

an additional member of the board. He is head of the coastwise and Continental sales department and foreign representative of the Union.

Messrs. Fuerst Brothers & Co., Ltd., announce that their Chairman, Mr. J. Fuerst, is retiring after 43 years' connexion with the company and its predecessors, Fuerst Brothers, of which he was one of the founders in 1884. His two sons, G. M. and H. R. Fuerst, are the remaining directors, and will carry on the company's business of chemical, oil and drug merchants as before.

The Consolidated Gold Fields of South Africa, Ltd., Gold Medal and Premium have been awarded by the Institution of Mining and Metallurgy to Dr. S. W. Smith, for his paper, entitled "Liquation in molten alloys and its possible geological significance."

The late Mr. T. Murdoch, J.P., chairman of the Employers' Federation of Bleachers, left £139,520, with net personalty £111,121.

The Pottery Inquiry

The Committee appointed to inquire into the application made by the British Pottery Manufacturers' Federation for the imposition of a Safeguarding duty on imported tableware of translucent pottery, has recommended that a duty of 28s. per cwt., on the net weight, should be imposed for a period not exceeding 5 years, on translucent and vitrified pottery used in connexion with the service of food and drink. The Committee consisted of three members, two of whom recommended that the application should be granted. The Committee concluded that nothing in the nature of "ring" prices exists in the industry; that the present unemployment in the industry is due to the importation of foreign china; and that, though some economies could be effected by co-operative working, the industry is carried on with reasonable efficiency and economy.

Light Leather Goods Inquiry

The Committee appointed to inquire into applications made by the National Leather Goods and Saddlery Manufacturers' Association for the imposition of a duty upon light leather bags and other receptacles, including bags and receptacles of materials made to resemble leather, and by the British Fittings Manufacturers' Association for the imposition of a duty upon metal frames, locks, and clasps for bags and other receptacles, has concluded that a case for a duty has not been made out.

The Sugar Industry

At a meeting of the Empire Sugar Section of the British Empire Producers' Organization, which represents the entire sugar-producing industry of the British Empire, it was unanimously decided to constitute the section into a federation. The objects of the federation are "to promote the interests of the sugar industry of the Empire and to collect information in regard to all matters relating to methods of production, transport, and marketing; to carry out a programme of propaganda and publicity with a view to increasing the production, sale, and consumption of Empire sugar; and to obtain such treatment for Empire-produced sugar as will secure stability and generally to take such action as may be considered desirable in the interests of the Empire sugar industry."

Sale of Chilean Nitrate

It is announced that free selling of Chilean nitrate will be permissible from April 14, 1927, but no nitrate sold under the free system may leave Chile before June 16, 1927. Therefore, nitrate sold under the free system will not be available in Europe until the middle of July, and so prices for the present season cannot be affected.

Municipal Coal-mining in Germany

The Frankfurt Gas Company and the Municipality of Cologne have purchased 11 coalfields from the Rheinische Stahlwerke A.-G. This is considered as a countermove to the proposed scheme of the Rhenish-Westphalian coal syndicate for the supply of heat and power for the whole of Germany from the Ruhr. The largest shareholder in the Rheinische Stahlwerke is the I.-G. Farbenindustrie, which has hitherto viewed the Ruhr power scheme with apprehension. The move is significant, as the Rheinische Stahlwerke is itself the third largest participator in the Rhenish-Westphalian coal syndicate.

Third Census of Production (Seed-crushing Trade)

In the following statement, particulars are given in respect of the quantity and value of the main classes of products manufactured during the year 1924 by firms engaged in the seed-crushing industry. The figures cover factories and workshops in Great Britain :-

Products	Sold or added to stock		
	Total Make In Year of Return	Quantities	Selling Value £
UNREFINED OILS	Tons	Tons	£
Cocunut	45,200	16,800	738,000
Cotton Seed	87,400	29,800	1,208,000
Ground Nut	29,100	18,500	850,000
Linseed	124,800	118,700	4,707,000
Palm Kernel	119,400	105,000	4,277,000
Rape Seed	25,500	15,800	616,000
Sesame	2,800	2,800	121,000
Soya Bean	16,300	4,600	176,000
Sunflower	6,400	6,200	279,000
Other Unrefined Oils	15,800	4,200	176,000
Total Unrefined Oils	472,700	322,400	13,268,000
REFINED OILS			
Cocunut		28,500	1,461,000
Cotton Seed		74,700	3,400,000
Ground Nut		11,500	619,000
Linseed			
Boiled ..		4,000	213,000
Refined ..		1,300	65,000
Palm		4,200	193,000
Palm Kernel		21,800	1,021,000
Rape Seed		9,600	447,000
Soya Bean		17,900	797,000
Other Refined Oils		12,600	716,000
Total Refined Oils		187,000	8,062,000
OIL-SEED CAKE AND MEAL			
Cotton Seed		413,000	3,253,000
Ground Nut		45,400	412,000
Linseed		271,000	3,163,000
Rape Seed		34,400	204,000
Soya Bean		80,900	835,000
Palm Kernel		116,400	796,000
Cocunut		79,200	254,000
Compound and Other Oil Seed cake and Meal (including Animal Feeding Stuffs unspecified)		463,500	4,485,000
Total Oil-Seed Cake and Meal		1,451,400	13,402,000
OTHER PRODUCTS			
Aid Oils			153,000
Black Grease			82,000
All Other Products			477,000
Total Value of Goods Made			£36,341,000

The quantities shown under the heading "Total Make in Year of Return" represent, without duplication, the total amount of each specified class of unrefined oil expressed during the year 1924, whether the oil was

subsequently refined by the firm by whom it was expressed, or was sold by that firm in an unrefined state. After taking into account the exports and imports of crude oil, it is practically certain that all the crude oil made in the United Kingdom and not refined by the original crushers was sold to manufacturers of soap, margarine, paints, etc., except in the case of cottonseed oil. With regard to the latter, either there was refined in 1924 an exceptionally large quantity of crude oil remaining in stock from previous years, or there was a duplication between the crude and the refined oil amounting in value to £1,000,000, or a little more. Further, the 463,500 tons of "Compound and Other Oil-Seed Cake" may include some cake bought (for mixing) from other makers and also included as output of the makers from whom it was bought, and to the extent to which this has occurred, duplication is involved. An additional 29,500 tons of cake and meal, shown on returns made by manufacturers of soap and candles, should be added to the 1,454,000 tons, shown above as produced in seed-crushing establishments in 1924.

During 1907 the output of oil, oil cakes and sundries totalled 1,371,000 tons, valued at £12,940,000, and other products totalled in value £21,000. Particulars of the quantity of the output for any class of seed oil or cake separately were not available in 1907. The total make of vegetable oils, unrefined in 1907, was 250,000 tons, compared with 472,700 tons in 1924, and of oil-seed cakes and meals the figures were 1,146,000 tons in 1907, against 1,454,400 tons in 1924. The development in crushing varieties of oil seeds and kernels not generally handled in this country before the war is clearly shown by these figures. Exports of unrefined oils in 1924 were 56,900 tons, of refined oils 25,500 tons, and of oil-seed cakes and meals 95,200 tons. The total quantity of oil-seed cakes and meals imported and retained for use was 24.8% of the total quantity manufactured in the United Kingdom, which was 1,454,400 tons, and the quantity of exports amounted to 6.5% of that quantity. The corresponding proportions for the year 1907 were about 30% and 2%, respectively. The net output of the factories employed in the industry was, in 1924, £3,832,000, the total estimated cost of materials used amounting to £32,512,000. The net output per person employed was £273 in 1924, and £180 in 1907. The average number of persons employed during the year was 14,027, compared with 7696 in 1907. The total capacity of engines at seed-crushing factories during 1924 amounted to 50,529 h.p., against 26,492 h.p. in 1907. In addition, in 1924, factories were also equipped with electric motors, driven by purchased electricity, aggregating 22,987 h.p. Electric motors aggregating 17,977 h.p. were returned in 1924 as driven by electricity generated in the firms' own works. About 7% of these motors were shown as in reserve or idle.

Castorseed Crop of British India, 1926-27

From information received from provinces and states which contain practically the whole area under castorseed in India, the total area reported is 1,372,000 acres, compared with 1,401,000 acres last year, a decrease of 2%. The yield is estimated at 132,000 tons, as against 144,000 tons last year, a decrease of 8%. The condition of the crop is, on the whole, reported to be fair.

REVIEW

THE SCIENTIFIC PRINCIPLES OF PETROLEUM TECHNOLOGY. By Dr. LEO GURWITSCH, translated and revised by HAROLD MOORE, M.Sc. Tech. Pp. xvi + 470. London: Chapman & Hall, Ltd., 1926. Price 25s. net.

Mr. Moore's translation of Dr. Gurwitsch's well-known treatise will be welcomed by English chemists interested in the physics and chemistry of petroleum. It is, perhaps, regrettable that the title chosen is quite misleading and gives one no correct idea of the nature of the book. Dr. Gurwitsch deals with few scientific principles and still less with petroleum technology, though his translator has inserted some sections more directly concerned with the industrial aspect of the subject. It is as an organic chemist that Dr. Gurwitsch approaches his subject, and as a treatise on the chemistry of petroleum and its components, this volume should be read by all chemists who are interested in this particularly complex mixture of organic chemicals.

The author makes no attempt to imitate that massive compilation "Das Erdöl," but he has collected a very large proportion of all the work that has ever been published on the physical behaviour and the chemical reactions of the constituents of the various fractions of petroleum. Works of this nature are too apt to consist of an uncritically assembled conglomerate of other peoples' statements, but this is an agreeable exception; the author is sufficiently an expert to be able to review, and where necessary to criticise, the opinions and results he quotes.

The book is divided into five principal sections:—(1) The constituents of petroleum and the action of various reagents on the products. (2) The physical properties of the constituents of petroleum. (3) The distillation of petroleum. (4) The refining of petroleum distillates. (5) The physical and chemical properties of the products.

The first section is the largest, and is concerned mainly with the identity of the compounds constituting petroleum and with the effect of various chemical reagents upon them. The hydrocarbons naturally receive the greatest amount of attention, whilst the oxygen compounds, which have been studied to a greater degree in Russia than elsewhere, are also fully described. Russian oil is not notably sulphurous, and the three-page section on sulphur compounds is decidedly inadequate, certainly not up to date. Much important work on the isolation and properties of these compounds has been published since Mabery's isolation of the "thiophanes" (which the translator describes as "hydrated" thiophens).

The section on the physical properties of petroleum (including a good chapter on surface tension and emulsions) is well written and full of interesting and useful information. The section on distillation consists largely of a survey of cracking and the effect of experimental conditions on the nature of the product; this survey is made from the chemical and not the technical or commercial aspect, though the more well known of the modern processes are briefly described. The concluding section deals with the chemistry and physics of refining,

the chemistry being mainly an account, very exhaustive and informative, of the action of sulphuric acid under all variations of experimental conditions on the various commercial fractions of petroleum. The chapter on adsorption and its application to the selective removal of specific types of petroleum components bears the mark of an authority on this subject.

Dr. Gurwitsch's book is undoubtedly the best treatise on the chemistry of petroleum in existence, and it should be in the library of every chemist who specialises in this material.

F. B. THOLE

PARLIAMENTARY NEWS

White Lead Paint

Answering Mr. Rhys Davies, Earl Winterton said that a letter had been communicated to the Government of India from the Federation of British Industries, suggesting that as the British Government had now decided to regulate, instead of prohibit, the use of white lead in paint, the Bombay Government should cancel its prohibitive instructions. In March, 1926, the Government of India drew the attention of local Governments to the proposals of the British Government, but the present attitude of the Bombay Government on the matter was not yet known. As regards the Convention generally, the difficulty the Government of India felt in putting it into operation was that it was impossible for any Government to control the hundreds of thousands of small painters who had been working in the past. It was therefore suggested by the Government of India that there should be a modification of the original Convention.—March 28.

British Industries Fair

In reply to Mr. Williams, Sir Burton Chadwick said that the space let to exhibitors amounted approximately to 176,000 sq. ft., and the rent paid was £22,000. A contribution of £3,000 per annum was made from the fair funds to cover both the services of the Exhibitions Divisions of the Department and all overhead charges. The whole of the correspondence connected with applications from would-be exhibitors was dealt with by special staff engaged for the fair, and paid for out of fair funds, general inquiries only being dealt with in the general registry of the Department. The whole cost of the staff employed in connexion with the fair was recovered from receipts from exhibitors, and involved no charge to the taxpayer.—March 28.

Food Preservatives

Replying to Mr. Campbell, Mr. Chamberlain said that he did not propose to issue to local authorities a suggestion that they should warn consumers that certain foods should not be expected to keep so long, owing to the absence of preservatives. In making the Regulations, however, the circumstances of the ordinary household, and the fact that most of the principal foods affected were already being sold without preservative by some traders, had been remembered.—March 31.

Fuel Research

The Duchess of Atholl informed Lieut.-Colonel Watts-Morgan that one of the duties of the Intelligence Section of the Fuel Research Division of the Department of Scientific and Industrial Research was to keep in touch

with the more important developments of fuel research in other countries, and a great deal of useful information had been obtained.—April 4.

Replying to various questions, the Duchess of Atholl stated that the net amount spent by the Department of Scientific and Industrial Research on fuel research in 1925–26 was £76,547, and during 1926–27 about £88,000. The products obtained from a ton of coal by the latest experimental treatment varied according to the process adopted and the coal used. It was impossible to give reliable commercial values for the by products until they had been available for purchase in large quantities over an extended period. During 1926 the coal used for experimental purposes by the Fuel Research Board amounted to 1541 tons of nuts, 2501 tons of run of mine, and 518 tons of smalls. The run of mine consisted of large and small in about equal proportions. It was sometimes used as received, and sometimes screened, according to the investigation in progress. The Prime Minister was not prepared to direct that a definite sum should be set aside for the purpose of research into the uses of oil for power production, since in these matters the Lord President was advised from time to time by his Advisory Council for Scientific and Industrial Research.—April 5.

In a written answer to Mr. Walsh, Colonel Lane Fox stated that the colliery owners had a national research association, and many of them were associated with the research work of the Institution of Mining Engineers. Locally, there was a Lancashire and Cheshire Coal Research Association, and in this and other coalfields some of the colliery owners, individually and through their associations, co-operated in research work carried on at the universities and by the local institutions of mining engineers. He had no information as to the amount spent.—April 6.

Lord E. Percy informed Mr. Lawson that coal for the experimental work of the Fuel Research Board had been drawn from the following coalfields in Great Britain :

• Northumberland and Durham, Lancashire, Yorkshire, Nottinghamshire and Derbyshire, North Staffordshire, South Staffordshire, Leicestershire, South Wales, Kent, Lanarkshire, Stirling, and Linlithgow. Arrangements were being made for a test on some Somerset coal to be carried out shortly. April 7.

Experimental Lactose Factory, Haslington

Mr. Guinness informed Mr. Lansbury that the total cost of the experimental factory at Haslington, which was established to investigate the problem of the utilisation of whey, was £43,600, including maintenance charges of £12,700 during the period 1918–26; it was sold by public tender for £3000 as from March 1, 1926. The cost of the experiment to the exchequer was therefore £40,600. An account of the work done at the factory, and of the solution which was obtained of the problem before it, had been published by the Ministry of Agriculture.—April 6

COMPANY NEWS LEVER BROS., LTD.

The net profit for 1926 amounted to £4,899,966, after providing for depreciation and allowing £463,465 for

debenture interest, compared with £5,501,556 for 1925. The preference and preferred dividends absorbed £3,895,528, and the balance of £4437 has been placed to reserve, as against an allocation of £661,343. Notwithstanding the depressing effect upon trade of the industrial disturbances during 1926, the total sales of soap were more than maintained. Steady progress was being made with the construction of the dock at Bromborough Port on the River Mersey, and with the development of the properties of the Huileries du Congo Belge. Three new soap factories, in Dublin, Buenos Aires and Sydney, N.S.W. respectively, were in course of erection, and were expected to be completed this year.

BRITISH DYESTUFFS CORPORATION, LTD.

The eighth ordinary general meeting was held on April 6, and was presided over by Lord Colwyn, deputy-chairman, in the absence, through indisposition, of the chairman, Lord Ashfield. In his prepared speech, which was read by Lord Colwyn, Lord Ashfield said he was conscious that he was addressing himself to a larger audience than was represented by the present shareholders of the company—namely, to those persons whose interests had now been merged with those of shareholders in other allied businesses in Imperial Chemical Industries, Ltd. The trading profits for the nine months, before providing for depreciation on plant and machinery, amounted to £82,931, which with the balance brought forward from the previous year, made an available sum of £160,939, from which £45,000 had been set aside for depreciation, leaving a net balance of £115,939. Even for a period of only nine months, this was not a satisfactory result by comparison with the previous year. When he last addressed the shareholders, we were at the beginning of what proved to be one of the most disastrous industrial disputes ever experienced in this country, and when he now reflected upon its length and extent, he wondered that the trade of the country was not more adversely affected. He wished that a better result could have been shown as a result of their trading activities, but he did not feel called upon to make any elaborate apology for the somewhat meagre amount realised under such circumstances, particularly in view of the fact that, though costs of production were materially higher, prices of dyestuffs have shown a continuous decline throughout the period. Every endeavour had been made, with some success, to increase efficiency and reduce expenditure, and he thought they could now claim that to-day they offered in their technical and commercial departments a service to the consumers of their dyestuffs in the textile and other industries which left little or nothing to be desired, and he also believed that their prices have been reduced to the lowest possible level under present circumstances. As regards payment of a dividend, it was possible that had no merger with other chemical undertakings occurred, the net balance of £115,939 mentioned above would have been carried forward and not distributed, but it was necessary to consider the interest of the shareholders connected with the Corporation prior to the amalgamation, and to have regard to the policy adopted by the other companies with which it had joined interests. Also, the Corporation had very ample resources in cash and investments and

it was not so necessary to carry forward a large balance; finally, the directors did not wish to go back from the start made last year by paying a dividend, and accordingly a dividend was declared of $2\frac{1}{2}\%$ per annum (less tax) for the nine months to December '31, 1926. As regards the merger in Imperial Chemical Industries, Ltd., the directors were gratified by the emphatic manner in which their decision to enter this important merger had been endorsed. Out of a total of 4,775,580 shares, only 47,818 shares had not been exchanged, many of which were held by persons resident abroad or by persons who could not be traced. The formation of Imperial Chemical Industries, Ltd., represented a determination to co-ordinate and develop the chemical resources of this country in a much more effective manner than has been possible in the past. It represented a new stage of industrial development within our Empire, whilst it fully recognised the obligations it carries not only to its shareholders, but also to consumers of its products and to the staff and workpeople it employs. The new company possesses a world-wide organisation and an unrivalled capacity for production in nearly all branches of the chemical industry, whilst its resources both in funds and personnel will enable it to enter into new fields of research in a manner which has hitherto been impossible to any single firm. The address was concluded by a short review of the earlier history of the Corporation since its formation in 1919 under the encouragement of the Board of Trade and of the principal colour-consuming industries, with the object of extending and concentrating the manufacture of synthetic dyestuffs in this country. It was no small scientific and commercial achievement that in spite of the handicaps under which the Corporation has laboured it has been able to develop from a small foundation a highly organised dyestuffs industry capable of giving an effective service to the colour users of this country. Those to whom the management of the Corporation had been entrusted during the past two or three years were not unappreciative of the patience and forbearance of the shareholders in the past, and they hoped that the measure of success which had attended their efforts, especially in connexion with the merger of the Corporation's interests with other and greater interests, had in some degree rewarded the shareholders.

SCHIMMEL AND CO.

This firm, which manufactures essential oils, flower ottos, natural isolates, synthetics, essences, etc., and has been the property of the Fritzsche family, Leipzig, for generations, has taken over by amalgamation the well-known concern in the same line of E. Sachsse & Co., of Leipzig. At the same time, it has been converted into a private limited company (registered capital £300,000 and ample reserves), the shares of which will remain in the family. Messrs. Schimmel & Co.'s business will be carried on as hitherto, the management remaining in the hands of the former owners, of whom the senior partner, Mr. Karl Fritzsche will act as chairman of the board, whereas Mr. Hermann Fritzsche will be the sole acting director of the limited company. Customers of Messrs. E. Sachsse & Co. will now be supplied exclusively from Miltitz near Leipzig.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
Acid Hydrochloric—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali—£6 15s. per ton, f.o.r. Special terms for contracts.
Bisulphite of Lime—£7 10s. per ton, packages extra.
Bleaching Powder—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4 ton lots.
Borax, Commercial—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride, Solid—£5—£5 5s. per ton, carr. paid.
Copper Sulphate—£25—£25 10s. per ton.
Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
Nickel Sulphate—£38 per ton d/d.
Nickel Ammon. Sulphate—£38 per ton d/d.
Potash, Caustic—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
Salammoniac—£45—£50 per ton. Chloride of ammonia £37—£45 per ton, carr. paid.
Salt Cake—£3 15s.—£4 per ton d/d. bulk.
Soda, Caustic, solid—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
Soda Crystals—£5—£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98%—£21 per ton. Sod. Bicarbonate (refined)—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate.—2½d. per lb.
Sod. Phosphate—£14 per ton, f.o.r. London, casks free.
Sod. Sulphate (Glauber's Salt)—£3 12s. 6d. per ton.
Sod. Sulphide conc. solid 60/65—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide—Golden.—6d.—1s. 5½d. per lb., according to quality.
Crimson—1s. 3d.—1s. 7½d. per lb., according to quality.
Arsenic, Sulphide, Yellow—2s. per lb.
Barytes—£3 10s.—£6 15s. per ton, according to quality.
Cadmium Sulphide—2s. 9d. per lb.
Carbon Bisulphide—£20—£25 per ton, according to quantity.
Carbon Black—5½d. per lb., ex wharf.
Carbon Tetrachloride—£46—£55 per ton, according to quantity, drums extra.
Chromium Oxide, Green—1s. 2d. per lb.
Diphenylguanidine—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron".—£13 12s. 6d. per ton. f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—5s. 3d. per lb. •
 Zinc Sulphide.—1s. 1d. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—1s. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 4s.—4s. 3d. per gal., 60% O.P. Solvent, 4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8d. per lb. Crude 60's, 1s. 8d.—1s. 9½d. per gal.
 Acid Cresylic, 99/100.—2s. 6d.—2s. 8d. per gal. Steady 97/99.—2s. 2s. 2d. per gal. Pale, 95%, 1s. 10d.—2s. 2d. per gal. Dark, 1s. 9d.—2s. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 2½d.—1s. 3½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 4d. per gal., ex works in tank wagons; Pure, 2s.—2s. 3d. per gal., ex works in tank wagons
 Toluole.—90%, 2s. 1d. to 2s. 2d. per gal. Firm. Pure, 2s. 3d.—2s. 4d. per gal.
 Xylol.—2s. 1d.—2s. 6d. per gal. Pure, 3s. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 9d.—9½d. per gal., according to quality. Solvent 90/160, 1s. 8d. per gal. Solvent 95/160, 1s. 7d.—1s. 8d. per gal. Solvent 90/190, 1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £8 per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—80s.—85s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—9s. 6d.—10s. per gal. Nominal. 90/180—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4).—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.
 Aniline Salts.—7d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4d. per lb. Fair enquiry.
 m-Cresol 98/100%.—2s. 8½d. per lb. Only limited enquiry.
 p-Cresol 32/34° C.—2s. 8½d. per lb. Only limited enquiry.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—2s. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb. ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb. Firm and brisk.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s. 3d. per oz.; 500 oz. lots—1s. per oz.
 Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 5½d.—1s. 5¾d. per lb. Less 5%. Firm.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 3½d.—1s. 4½d. per lb. Technical 11½d.—1s. per lb. Both in good demand.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 2d. per lb. Less 5%. Firm market.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 6d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb. Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 4d.—2s. 6d. per lb. Potassium.—1s. 11d.—2s. 1d. per lb. Sodium.—2s. 2d.—2d. 4d. per lb. All spot.

Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Creosote Carbonate.—6s. per lb.

Ether meth.—1s. 1d.—1s. 1½d. per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiacol Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 5d. per gal. f.o.r. makers' works, naked.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb., for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron. Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—22s. per cwt., 112 lb. lots.

Magnesium Carbonate.—Light Commercial £33 per ton net.

Magnesium Oxide.—Light Commercial £67 10s. per ton, less 2½%; Heavy Commercial £22 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Monthol.—A.B.R. recryst., B.P., 18s. 9d. per lb. net. Synthetic, 11s.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb. Detached cryst., 14s. 6d. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonal.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—3s. per lb.

Phenazone.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar) 90s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferrieyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 2d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Resorcin.—4s. per lb. spot.

Saccharin.—55s. per lb. Very limited enquiry.

Salol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d.—per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net, according to quantity. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonal.—7s. 6d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.

Thymol, Puriss.—11s. 6d.—12s. per lb., according to quantity. Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (*ex Anethole*).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. 6d. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 3d. per lb.

Ethyl Cinnamate.—10s. per lb.

Ethyl Phthalate.—3s. per lb.

Eugenol.—9s. 6d. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—27s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb. Good demand.

ESSENTIAL OILS

Almond.—11s. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—12s. per lb.

Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb.

Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 3d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure—6s. per lb.

Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—10s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb.

Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 18s. 9d. per lb. Japanese, 8s. 6d. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The Complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than June 4th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on April 21st. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Borg. Filtration. 8655. Mar. 20.
Glossop and Hodson. Kilns. 8584. Mar. 29.
I.-G. Farbenind. Preparation of emulsifying-agents. 8475. Mar. 28. (Ger., 27.3.26.) Manufacture of decomposition products etc. 8477. Mar. 28. (Ger., 3.4.26.)

Johnson (I.-G. Farbenind.). Production of gases. 9133. Apr. 2.

Metropolitan-Vickers Electrical Co., Ltd., and Bailey. Heat treatment of pulverulent materials. 8644. Mar. 29.

Semet-Solvay Co. Distillation systems. 9017. Apr. 1. (U.S., 17.4.26.)

I.—Complete Specifications

32,778 (1925). Wisner. Rotary furnaces. (246,118.)
32,800 (1925). Campbell. Apparatus for separating solids from liquids. (268,051.)

13,436 (1926). Excelsior Feuerlöschgeräte. Producing foam for fire-extinguishing. (252,727.)

14,842 (1926). Johnson (I.-G. Farbenind.). Feeding solids and gases into reaction vessels under pressure. (268,188.)

15,613 (1926). Grisco-Russell Co. Heating or cooling viscous liquids. (256,579.)

25,283 (1926). Meister. Drying-apparatus. (268,237.)

27,520 (1926). Bentley. Tube and like mills. (268,245.)

30,685 (1926). Vernay. Rotary drying-apparatus. (262,464.)

31,903 (1926). Siemens Schuckertwerke. Crucibles. (263,171.)

32,837 (1926). Loesche. Grinding-mills. (268,263.)

32,842 (1926). Albas-Chalmers Manufacturing Co. Comminuting-mills. (268,264.)

2270 (1927). Mercier. Apparatus for condensing vapours and extracting non-condensable gases. (265,199.)

*8007 (1927). Bergl and Dietrich. Production of cold. (268,358.)

*8460 (1927). Cerini. *See* VII.

*8475 (1927). I.-G. Farbenind. Emulsifying agents. (268,387.)

II.—Applications

Chambers. Purifiers for manufacture of gas. 8986. Apr. 1.

I.-G. Farbenind. Conversion of hydrocarbons of high boiling point into compounds of low boiling point. 8890. Mar. 31. (Ger., 1.4.26.)

Mallery. Utilising residue oils containing water. 8983. Apr. 1. (U.S., 5.4.26.)

Ringrose. Apparatus for detecting etc. inflammable vapours. 8975. Apr. 1.

Salerni. Treatment of hydrocarbon gases etc. 8481. Mar. 28.

Synthetic Ammonia & Nitrates, Ltd., and Horsley. Process of separating and recovering olefins from gases. 8705. Mar. 30.

III.—Complete Specifications

30,225, 23,985, and 30,307 (1925). Bonniksen and Barratt. Production of flame or smoke for signalling and smoke-screen purposes. (268,004.)

*31,520 (1925). Bone, Quirendon, and Gas Light & Coke Co. Manufacture of products by oxidising coal. (268,006.)

31,929 (1925). La Raboisiere. Fuels. (244,797.)

32,438 (1925). Siemens A.-G., and Bahr. Recovering sulphur compounds of ammonia from gas mixtures. (268,024.)

28,803 (1926). Lasmolles. Gas producers. (262,088.)

*25,872 (1926). Bensmann. Regeneration of lubricating-oils. (268,284.)

*6811 (1927). Seelig. Cracking oils. (268,323.)

*8268 (1927). Koppers Co. Manufacture of coal products. (268,372.)

III.—Application

I.-G. Farbenind. Production of conversion products of tars etc. 8476. Mar. 28. (Ger., 30.3.26.)

IV.—Applications

Carmichael (I.-G. Farbenind.). Manufacture of compounds of thiazolic series. 8789. Mar. 30.

Holliday & Co., Ltd., Kitson, and Shaw. Production of dyestuffs. 8685. Mar. 30.

I.-G. Farbenind. Manufacture of diazotised amines of the cyclic series. 8771. Mar. 30. (Ger., 30.3.26.) Manufacture of azo dyestuffs. 8931. Mar. 31. (Ger., 31.3.26.)

Imray (I.-G. Farbenind.). Manufacture of sulphur dyestuff. 8624. Mar. 29.

Scottish Dyes, Ltd., Smith, and Thomas. Dyestuffs etc. 9053. Apr. 1.

V.—Applications

Angel. Manufacture of cellulose. 9144. Apr. 2.

Bemberg A.-G. Manufacture of artificial silk. 8543. Mar. 28. (Ger., 27.3.26.)

Clavel. Treatment of artificial silk. 8784. Mar. 30.

Deutsche Zellstoff-Textilwerke Ges. Treating artificial silk. 8658. Mar. 29. (Ger., 30.3.26.)

Lucas, and Vickers, Ltd. Preparing fibrous vegetable materials. 9145. Apr. 2.

Silver Springs Bleaching & Dyeing Co., and Hall. Treating viscose silk. 8716. Mar. 30.

Verein f. Chem. Industrie. Recovery of acetic acid from acetyl cellulose. 8495. Mar. 28.

V.—Complete Specifications

*31,737 (1926). I. G. Farbenind. Manufacture of cellulose esters. (268,289.)

*8543 (1927). Bemberg A.-G. Manufacture of twisted artificial silk. (268,393.)

VI.—Application

Heberlein & Co. Producing pattern effects on textile goods. 8501 and 8623. Mar. 28 and 29. (Ger., 27 and 30.3.26.)

VI.—Complete Specifications

*7076 (1927). Adolph and Pietzsch. Bleaching. (268,325.)

*7189 (1927). Soc. Anon. Etabl. Petitdidier. Dyeing fabrics containing immunised cotton fibres. (268,327.)

*8147 (1927). Soc. Chem. Ind. in Basle. Manufacture of artificial forms or threads fast to water and easily dyed. (268,363.)

*8501 (1927). Heberlein & Co. Producing pattern effects on textiles. (268,389.)

VII.—Applications

Cerini. Purification of caustic soda etc. 8460. Mar. 28. (Italy, 26.3.26.)

Colombo. Chambers for manufacture of sulphuric acid. 8894. Mar. 31. (Spain, 6.5.26.)

Gerlach. 8741. *See* XI.

Goldschmidt and Goldschmidt. 8783. *See* XVIII.

I.-G. Farbenind. 8892. *See* X. Catalytic production of hydrocyanic acid from formamide. 9002. Apr. 1. (Ger., 10.4.26.) Manufacture of alkali bisulphate. 9035. Apr. 1. (Ger., 1.4.26.)

Kaiser and Lichtenberger. Manufacturing finely distributed barium sulphate etc. 8607. Mar. 29. (Ger., 3.4.26.)

Metallbank und Metallurgische Ges. A.-G. Treating lithium-containing silicates. 8943. Mar. 31. (Ger., 22.4.26.)

Verein f. Chem. Industrie. 8495. *See* V.

VII.—Complete Specifications

29,096 (1925). Lambert. Manufacture of potassium nitrate. (267,996.)

32,046 (1925). Haddan (Celite Co.). Manufacture of silicious alkaline earth compounds. (268,011.)

32,509 (1925). Deutsche Gold- u. Silberscheideanstalt. Production of concentrated solutions of alkali cyanides. (245,152.)

5218 (1926). Bentley, and Blythe & Co., Ltd. Manufacture of lead nitrate. (268,104.)

13,831 (1926). A.P.I.C.E. Soc. Anon. Prodotti Ital. Chim. Estrattivi, and Gasparrani. Manufacture of sodium chloride. (268,181.)

16,394 (1926). Rhenania Verein Chem. Fabr. Manufacture of moulded sulphur. (265,540.)

*4002 (1927). New Jersey Zinc Co. Manufacture of zinc oxide. (268,301.)

*4881 (1927). Collin A.-G. Discharging ammonium sulphate from saturating tanks. (268,309.)

*8460 (1927). Cerini. Apparatus for purifying impure solutions of caustic soda etc. (268,385.)

VIII.—Applications

British Thomson-Houston Co., Ltd. Apparatus for producing silica articles. 8609. Mar. 29. (U.S., 1,426.)

Despret. Continuous manufacture of molten and refined glass. 9056. Apr. 1.

VIII.—Complete Specifications

18,979 (1926). Gourdjian and Jones. Clay bodies for tiles etc. (268,204.)

29,514 (1926). Kruger. Process of producing cast articles, volcanic stones, etc. (262,413.)

IX.—Applications

Knibbs. Production of cementitious material. 9054. Apr. 1.

Soc. Le Nylum. Manufacture of magnesia cements. 9126. Apr. 2. (Fr., 16,426.)

IX.—Complete Specification

32,046 (1925). Haddan (Celite Co.). See VII.

X.—Applications

Allgem. Elektrizitäts-Ges. Production of metallic coatings upon non-conducting oxides. 9021. Apr. 1. (Ger., 1,426.)

Aluminum Co. of America. 8502. See XIII.

Aumund. Blast furnaces. 8864. Mar. 31. (Ger., 31,326.)

Blumey. Extraction of metals from ores. 9081. Apr. 2.

Boumphrey. Preventing corrosion of metals. 8819. Mar. 31.

Glennell. Extraction of cobalt and nickel. 9094. Apr. 2.

Ellis (Granular Iron Co.). Rail steels. 9143. Apr. 2.

Garnet, Holden, and Smith. Heat resistance alloys. 8649. Mar. 29.

Hofmann. Ore smelting. 8657. Mar. 29.

I.-G. Farbenind. Precipitation of heavy metals from ammoniacal solutions. 8892. Mar. 31. (Ger., 9,426.)

Minerals Separation, Ltd. (Beasley and Tiplin). Leaching ores. 9041. Apr. 1.

Ozberger. Alloy. 8900. Mar. 31. (Austria, 3,426.)

X. Complete Specifications

7560 (1926). Ellis, and United Steel Co. Treatment of steel ingots. (268,123.)

18,262 (1926). Corson. Copper alloys. (268,200.)

18,333 (1926). Job. Treatment of zinc ores etc. (268,201.)

23,318 (1926). Metallbank u. Metallurgische Ges. Copper alloys. (268,225.)

*16,842 (1926). Zinnwerke Wilhelmsburg Ges. Treating anthracite ores, especially tin ores. (268,278.)

*4262 (1927). New Jersey Zinc Co. Metallurgical operations. (268,302.)

*4516 (1927). Polanyi and Bogdandy. Determining the composition of copper and zinc alloys. (268,306.)

*6027 (1927). Lacell. Production of magnesium. (268,316.)

XI.—Applications

Allgem. Elektrizitäts-Ges. 9021. See X.

Fromont. Electric accumulators. 9147. Apr. 2. (Fr., 2,426.)

Gerlach. Electrolytic cells for decomposition of alkali chlorides. 8741. Mar. 30. (Ger., 17,426.)

Gjerulff. Galvanic cells. 8710. Mar. 30.

Standard Telephones and Cables, Ltd. Magnetic core materials. 8464. Mar. 28. (U.S., 17,426.)

Materials. 8465. Mar. 28. (U.S., 17,426.)

Vultex, Ltd. 8942. See XIV.

XI.—Complete Specifications

32,220 (1925). Billiter, and Siemens & Halske A.-G. Electrolytic filter diaphragms. (245,127.)

32,718 (1925). Mierow. Galvanic batteries. (268,047.)

30,795 (1926). Billiter, and Siemens & Halske A.-G. Electrolytic filter diaphragms. (262,470.)

*8176 (1927). Aletter. Producing electric lead accumulators. (268,366.)

XII.—Application

Industrial Spray-Drying Corp. Manufacture of soap powder. 8960. Apr. 1. (U.S., 19,426.)

XII.—Complete Specifications

29,673 (1925). Charlton, and Rowe & Co., Ltd. Manufacture of soap. (267,999.)

*6598 (1927). Maschinenfabr. Elite A.-G. Manufacture of soap flakes. (268,320.)

XIII.—Applications

Aluminum Co. of America. Production of corrosion-resistant articles. 8502. Mar. 28. (U.S., 22,127.)

Comp. Lorraine de Charbons, Lampes, et App. Electriques. Treatment of pulverulent fillers and pigments etc. 8480. Mar. 28. (Fr., 10,526.)

Kalbitum Paint Co., Ltd. Paints etc. 9118. Apr. 2.

XIV.—Applications

Barrows. Rubber etc. 8603. Mar. 29.

Dunlop Rubber Co., Ltd., and Thornton. Manufacture of articles from aqueous dispersions of rubber etc. 8582. Mar. 29.

General Rubber Co. Apparatus for drying rubber latex etc. 8470. Mar. 28. (U.S., 10,426.)

Vultex, Ltd. Production of caoutchouc articles etc. by electrodeposition. 8942. Mar. 31. (Ger., 5,726.)

XIV.—Complete Specifications

12,609 (1926). Kodak, Ltd. Coating materials with rubber. (261,700.)

22,359 (1926). General Rubber Co. Preserving latex. (268,219.)

*2764 (1927). Nantux Chemical Co. Treating latex. (268,299.)

XV.—Applications

Arnold (Laucks, Inc.). Protein colloids etc. 8505. Mar. 28.

I.-G. Farbenind. Hardening plastic masses from casein etc. 8922. Mar. 31. (Ger., 31,326.)

Matthews. Impregnating leather with wax etc. 8674. Mar. 29.

XVI. Application

Liljenroth. Production of manures. 8628. Mar. 29. (Sweden, 14,126.)

XVI.—Complete Specification

*32,802 (1926). Bennett. Treating seeds to augment their cultural value. (268,291.)

XVIII.—Applications

Commercial Solvents Corp. Butyl-acetonic fermentation. 8535. Mar. 28. (U.S., 1,1026.)

Goldschmidt and Goldschmidt. Obtaining concentrated potassium solutions from distiller's mash. 8783. Mar. 30. (Czecho-Slovakia, 30,326.)

Sak. Production of compressed yeast. 8932, 9028, 9029. Mar. 31 and Apr. 1.

XIX.—Applications

Arnot. Treatment and utilisation of animal blood etc. 8651. Mar. 29.

Posternak. Obtaining total nuclei of proteids of egg yolk. 8929. Mar. 31. (Switz., 31,326.)

Posternak and Posternak. Separating and purifying phosphorus nuclei of proteids in egg yolk. 8930. Mar. 31. (Switz., 31,326.)

Vautin. Preservation of eggs. 8670. Mar. 29.

XIX.—Complete Specifications

9047 (1926). Vidal (Anderson-Barngrover Manufacturing Co.). Treatment of condensed or evaporated milk. (268,138.)
26,219 (1926). Vietinghoff. Obtaining extractives from coffee. (268,241.)

XX.—Applications

Commercial Solvents Corp. 8535. See XVIII. Catalysts for synthesis of methanol. 8536. Mar. 28. (U.S., 25,10,26.)
Dehn (Chem. Pharm. A.-G. Bad Homburg). Production of solutions of basic quinine. 8888. Mar. 31.
Haskell. Solvent for essential oils etc. 8463. Mar. 28.

XX.—Complete Specifications

11,083 (1926). Thiermae. Separation and purification of vanillin. (268,158.)
*8285 (1927). I. G. Farbenind. Manufacture of alkylated or cyclo-alkylated arylsulphonic acids. (268,375.)

XXI.—Complete Specification

10,595 (1926). Silver Springs Bleaching and Dyeing Co. Ltd., and Hall. Development of photographic plates, films, and the like. (268,155.)

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*British India*: Boilers, steel boiler tubes (The South Indian Railway Co., Ltd., 91, Petty France, London, S.W.1); Acetone (Director General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *Canada*: Lubricating apparatus (342a). *Greece*: Carbon paper, typewriter ribbons (357). *Norway*: Cattle feeding stuffs (361). *South Africa*: Earthenware, glassware (348); cast iron pipes (A.X. 4520); steel pipes (A.X. 4519).

Safeguarding of Key Industries

The Board of Trade give notice that representations have been made to them under Section 10 (5) of the Finance Act, 1926, regarding the article, Urea.

Section 10 (5) of the Finance Act, 1926, is as follows:—

"The Treasury may by order exempt from the duty imposed by Section 1 of the Safeguarding of Industries Act, 1921, as amended by this Act, for such period as may be specified in the order, any article in respect of which the Board of Trade are satisfied on a representation made by a consumer of that article that the article is not made in any part of His Majesty's Dominions in quantities which are substantial having regard to the consumption of that article for the time being in the United Kingdom, and that there is no reasonable probability that the article will within a reasonable period be made in His Majesty's Dominions in such substantial quantities."

Any person desiring to communicate with the Board of Trade with respect to this application should write to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George Street, S.W.1, within one month from the date of this notice (April 6, 1927).

New Dyestuffs

A new pattern card No. S.C.68, published by the British Dyestuffs Corporation, shows a valuable addition

to the B.D.C. range of sulphur colours, in Thionol Brown CL4R. Unlike many of the usual bright red browns on the market, it possesses very good fastness to light, washing, alkalis, acids and cross-dyeing. The shade is practically unaffected by after-treatment with chrome and copper. It is applicable to all forms of cotton materials, and is suitable for dyeing in circulating machines.

A further addition to the B.D.C. chrome colours is "Solochrome Brown RH," which gives full reddish brown shades and possesses an additional advantage of being in powder form. It leaves cotton effects white. It is of interest for the dyeing of all forms of wool materials, and, owing to its very good fastness to light, good fastness to milling and levelling power, it is specially suitable for dyeing loose wool, slubbing and piece intended for the manufacture of suitings. In addition it is of interest for dyeing shoddy.

News from Advertisements

The Department of Scientific Research announces a vacancy for an analyst in the Building Research Station (p. viii).

A chemist is wanted for practical inorganic and physical chemical research (p. viii).

Technical chemist or chemical engineer with experience in the manufacture and blending of tanning extracts is wanted (p. viii).

The University College, Cork, invites applications for a vacant professorship and vacant lectureships (p. viii).

The University of St. Andrews draws attention to the Scholarships and Bursaries open to competition in June, 1927 (p. viii).

EDITORIAL

Research Associations

READING through the Report of the Privy Council for Scientific and Industrial Research more at our leisure, we found ourselves regretting that two additional research associations at least, namely, those to work for the benefit of the portland cement and paper-making industries, were not in active being. Neither of these important industries is actually languishing, but it can surely not be held that nothing remains to be discovered which shall be of value to them. In both instances it is true that mechanical and engineering skill has been largely responsible for lowering the costs of production, and the manufacturer naturally pays great heed to improvements in plant and equipment. In the cement industry, producing after a hundred years at the rate of around four million tons of cement a year, more than twice as much capital per man employed is invested as compared with the average for all other industries, and the manufacturer appears ready to spend still further upon improved kilns, clinker coolers, grinding mills, mechanical conveyors and packing machines, dust filters and electrical drive mechanism. He is ready, too, to march with the times when he realises that the recovery of heat from kiln gases by means of waste-heat boilers may be sufficient to generate the whole of the electrical power required throughout the cement plant. It is, therefore, the more difficult to understand why the study of fundamentals is so neglected not only upon the purely chemical side, but also in the matter of important engineering problems. Dr. Martin said in a paper which we published a few months ago upon

"Some recent researches in the science of fine grinding," that although the subject was of great importance to the cement industry, which spent over a million pounds annually upon grinding clinker, the scientific work striking at the very basis of the problem

was carried out in most worrying and discouraging circumstances. The Government withdrew their grant long before the British Portland Cement Research Association was on its feet, while the cement trade itself was openly hostile." In matters chemical, too, there appears to be the same lack of enterprise. The state of combination which exists amongst the lime,

silica and alumina in portland cement is still unknown, and who may say what will come of a full study of this problem. Already it is known that by using a different "raw mix" containing more than the usual proportion of alumina the rapid hardening high strength cement of the type of the French fused cement can be made, and that by paying full attention to materials, control, and extreme fine grinding of clinker similar portland cements can be produced as, for instance, in the case of the British "Ferrocrete." By controlling the cement-water ratio during the making of concrete, American investigators have shown us how to make better concrete with less cement. But we shall not be expected to tabulate a series of researches bearing upon cement in order to press the claims of research. Organised research has been accepted as worth while by twenty-three Associations, and the cement industry, as a whole, is neither too poor, too highly organised within itself, nor too unscientific to neglect true research. At the recent annual meeting of the Technical Section of the Paper Makers' Association of Great Britain and Ireland a very satisfactory financial position was revealed. The manufacturers who so willingly support their own Association should surely support their own Research Association, assisted by the Department for Scientific and Industrial Research, for all that appertains to the science of paper making is not yet revealed. The value and methods of applying the various sizes, the use of silicate of soda in paper making—an address upon which subject was given at the above-mentioned meeting by Mr. Rex Furness—the matter of fibre hydration, the resistance of papers to aqueous and oily ink penetration, and a variety of problems of general interest and importance to the paper-maker can best and most economically be tackled by a central research organisation. Is it not possible to resurrect the Portland Cement Research Association and to create a Paper-makers' Research Association under the auspices of the Department of Scientific and Industrial Research?

Colour

We recently took a rash resolve that, this Easter at least, chemistry should be laid aside and forgotten for

a short while. We had no visions of tramping moors or of sliding smoothly along mirrored rivers; the salty tang of the sea or the moan of the saxophone did not lure us. But we had visions of a little patch of earth which suffers from the too kindly shade of ancient trees and the attentions of the local fauna and flora, and grows far too many weeds to satisfy our requirements of orderliness. Weeds, we once were told, are plants which are growing out of place—and so a recent morning, glorious with Spring's freshness, saw us labouring hard to control the stubborn earth. As we paused a moment to rest, we reflected that Finsbury Square for once seemed far away, that the sun was hard at work activating our ergosterols. The saucy eye of a gay robin which came to inspect our handiwork reminded us that, already, we had broken our resolve. Chemistry was still with us, and we were reflecting upon the problems of colour. The robin continued to watch us, delightfully poised on a twig, and as we admired his plumage, we mentally tried to match it with artificial colours. A very good match could be made, we thought, but how unlike the reality. Have we really the power to match Nature's hues exactly? Would not the spectral transmission be often different, and would not there be divergence of opinions about the correctness of the matching if the light happened to vary. A standard of colour is still wanted, a number which will express a colour so exactly that it could be reproduced with spectroscopic accuracy without reference to changeable samples. Other forms of vibrations such as heat and electricity can be made to do work and so can be standardised accurately, but light and colour and sound seem, as far as we are aware, to elude the grip of exact standardisation. Much can be done, we know, by the aid of empirical standards for comparison of colours, but the possession of an exact method of definition would be of immense value to several industries. The Society of Dyers and Colourists, and some of the research associations, are devoting some attention to problems such as the standardisation of colours, and we hope that it will not be long before we can record that a completely satisfactory solution has been reached. The human eye is a wonderful instrument. It makes a very good pyrometer when its owner has had sufficient experience: if it is of the right kind, it can be used with considerable advantage to its proprietor in the dyeing trade; and its sensitivity is greater than that of even the most rapid photographic plate. But it suffers from the vagaries to which the biochemistry of the body is subject, and on occasion it can be very much "out," and then material may be spoiled. Some of the light-sensitive cells are used for the purpose of photometry, but we wonder if they find any application connected with colour. We know very little about such cells, though we are aware that selenium is used in some of them. The New York Public Library has recently published a list, costing 65 cents, and covering nearly one hundred pages of references to the whole literature of selenium from 1817 to 1925. The list includes some 30 pages of titles of papers and patents relating to the optical and electrical properties of selenium and to its industrial applications. It seems very suggestive. But our reflections were suddenly stopped, as the robin got tired of waiting for a fresh patch of soil to be turned, and so flew away.

THE PROBLEM OF SEPARATION IN THE CHEMICAL INDUSTRIES

The two chief problems of separation occurring in the chemical industries are those of separating solids from solids and solids from liquids. The commonest method of separating solids from solids is by sizing, which is carried out wet or dry by a wide range of screening and sifting devices.

The dry separation of solids from solids is commonly carried out by screening, a process well known to every engineer. A recent development in screening is the use of electrical vibrating screens, in which the screening surface is vibrated at a very high speed so as to assist the process of mechanical separation. These screens are used for the separation of very fine substances, a purpose for which other processes, viz., air and water currents, have been found useful. In such plant, horizontal currents of water carry along the fine particles or light particles and leave the heavier and larger particles behind. An instance of this method of separation is found in the cleaning of coal by the Rheolaveur process, in which the coal is carried along a trough by the current of water, and the shale and stone sinks to the bottom, being withdrawn at intervals through traps.

In separators employing air currents, a vertical current of air carries the finer particles upwards and leaves the heavier particles behind. This process is applicable to the cleaning of fine felspar, talc, and pulverised coal.

In processes such as these, successful operation depends upon differences in specific gravity, and in many cases separation is not reliable. In the chemical industry, such separation is often carried out in water, or in air, the fundamental principles being the same and the apparatus being similar. In other cases—for instance, the jig separator—the mass of material is subjected to vertical pulsations, alternating with suction of air or water, the result being that the heavier matter stratifies underneath the lighter. This method gives good results in its later modifications, though it cannot be said to be 100% efficient.

Another method is to use a table with an inclined surface, on to which the material is fed, together with water, at the top. In this apparatus the heavier material lags behind the lighter particles. In addition, the larger particles are floated down more quickly than the smaller particles, so that separation of two kinds may be carried out on apparatus which is both cheap and simple. In other cases the tables have a bed of pulp or a mixture of solid and water, and a shaking motion serves to keep the pulp mobile. The result is that stratification takes place, and the lighter stratum is washed off by a current of water, whilst the heavier matter is carried on and ejected at the end of the table.

In other methods of separating solids from solids, a liquid medium of specific gravity intermediate between that of the two solids is used as a floating medium, the result being that one solid will float and the other will sink. For instance, a solution of zinc chloride can be employed to separate coal from slate. A process which employs the same principle is the Columbus coal separator, in which a mixture of water and clay is used, the coal floating and being carried off continuously, while the slate

sinks to the bottom. In the Chance process, the separation solution is an intimate mixture of sea sand and water, which is continually agitated. The coal, floating on the top, is carried off the surface by a current of water, while the slate sinks to a lower strata. In each of these processes the specific gravity of the separating solution is easily regulated.

The flotation process is another process which first was used for ores, and has now been employed for separating coal from slate. In this a certain amount of reagent is mixed with water and the material to be separated. These reagents reduce the surface tension of the liquid and, with suitable agitation of the entire mixture, air or gas bubbles are formed, which carry such substances as mineral sulphides, coal and graphite to the surface in a scum or froth, while the waste particles sink to the bottom of the vessel. This process is, of course, applicable only to very fine particles, say about $\frac{1}{4}$ mm. in size, or below 50 mesh.

An even later method of dry separation, which has the advantage over flotation that the materials have not to be dried subsequently, is air separation, which has proved very successful in dealing with such substances as coal below about 2 inches in size. The coal is fed on to a table fitted with a perforated top, and a current of air, forced up through the perforations, carries the lighter particles to the top of the bed, while the heavier material remains at the bottom of the bed and slides off the table down inclined surfaces.

Other dry methods of separation are the spiral separator and the magnetic pulley. In the spiral separator, which depends upon specific gravity, the mixture is fed to the top of a series of spirals, and the heavier particles attain a greater velocity of descent, being finally thrown clear of the lighter. This method is being used successfully for separating coal from slate.

The magnetic separator is not a classifying medium, but a purifier, in that it removes magnetic substances which are liable to damage machinery or taint a finished product. An instance of this is the removal of iron scrap from coal and other substances to prevent damage to crushing machinery. The magnetic pulley consists of an end pulley on a belt conveyor, which attracts and holds magnetic substances until they are out of the main stream of the material and finally ejects the impurities into a bin under the conveyor. This process also presents the advantage that the material does not need subsequent drying, though it has been applied successfully to the treatment of substances in solution.

A method of separating solids from solids which has come very much to the front in recent years is the centrifugal separator. In this appliance the material is fed through a stationary feed pipe on to a revolving distributing plate, which throws it off in a thin sheet. The material is then caught by a rising current of air, and all but the heaviest particles are carried up to the centrifugal separating chamber, where the air carrying the fine particles is made to rotate by vanes fixed to the central shaft. The heavier particles are thrown against a screen, while the lightest particles of all are carried upwards into a separate chamber. In this way several degrees of classification are obtained. This apparatus has enabled great advances to be made in the

separation of very fine particles, and has made possible the commercial use of waste products; for instance, slate dust, which can now be reduced to a mesh fine enough to be used as a paint filler, and clay and marl fines as rubber fillers.

The separation of solids from solids has involved special study in the paper pulp industry, in that bundles of fibrous matter, knots, and metal parts have to be eliminated. During recent years a rotary screen has made its appearance, in which slotted copper plates fastened to a cylinder are revolved slowly in a vat of stock. The discharge is from the outside of the cylinder to the inside. The screening action is obtained by means of a cam or crank motion which oscillates the sides of the vat, causing the stock to be forced alternately towards the plates and away from them. This type of screen has proved very successful, and has taken its place with the centrifugal and the flat screens as an aid in obtaining pure pulp.

CANADIAN INDUSTRIAL NOTES

The announcement has been made that a British syndicate plans to spend \$500,000,000 in the next five years in industrial development of the Lake St. John district of Quebec. A railway will be built round Lake St. John, pulp and paper mills, smelters and iron furnaces constructed, the last-named for the magnetic iron ores of the district. Premier Taschereau has admitted that negotiations had been in progress for some time.

The William Cooke & Co. (Canada) will construct a large wire-rope plant on Granville Island, B.C. The machinery is being forwarded from England. All sizes of rope up to 3 inches will be manufactured. C. D. Hobbs, general manager of the Western Hardware & Steel Co., will be managing director.

The Canada Cement Co., Ltd., has purchased 24 gypsum properties on the north side of Antigonish Harbour, N.S., with good shipping facilities. Work will begin immediately, and docks for steamers of 10,000 tons constructed. The quarries will be equipped with crushers and storage facilities.

The largest cereal mill west of the Great Lakes is under construction by the Quaker Oats Co., at Saskatoon, Saskatchewan.

The Lumber Chemical Co., Ltd., of Penticton, B.C., manufacturers of insecticides etc., has recently incorporated the Oliver's, Limited, for the utilisation of by-products from the packing houses, manufacturing sweet cider, concentrated cider, vinegar, pectin, etc. Charles E. Oliver is manager and chemical engineer.

The passage of legislation for the sale of liquors, wines and beers, under Government control, by the Ontario Assembly has produced a boom in the stock of breweries and distilleries, and also in their erection. The Peace Bridge Brewing Co., Ltd., Bridgeburg, Ontario, has a million-dollar brewery under construction. Prominent Buffalo, N.Y. (across the river), financial men are interested. The management will be in their hands, and American lager will be the chief product.

British interests (not the Distillers Co., Ltd.) have acquired large holdings in the Seagram Distillery Co., Ltd., Waterloo, Ontario.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, JULY 4 to 8, 1927

In accordance with the provisions of By-law 68 notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Debating Hall, The Union, University of Edinburgh, on Tuesday, July 5, 1927, at 10 a.m.

A preliminary programme appeared on page 265 of CHEMISTRY AND INDUSTRY, for March 25, 1927, but a more detailed programme will be issued shortly.

In accordance with the provisions of By-law 23, notice is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting:—

Mr. Francis H. Carr, C.B.E., *President*; Dr. E. Frankland Armstrong, F.R.S., *Professor J. W. Hinchley*, *Professor J. C. Philip*, F.R.S., and *Sir Richard Threlfall*, K.B.E., F.R.S., *Vice-Presidents*. Mr. W. A. S. Calder, Mr. W. H. Coleman, Dr. William Cullen, and Mr. J. Arthur Reavell, *Ordinary Members*.

Mr. Francis H. Carr, C.B.E., has been nominated for re-election to the office of President under By-law 19. Mr. E. V. Evans, Mr. C. S. Garland, Dr. H. Levinstein, and The Right Hon. Sir Alfred Mond, Bart., M.P., have been nominated Vice-Presidents under By-law 20.

Dr. E. W. Smith has been elected Hon. Treasurer, and Dr. E. Frankland Armstrong has been elected Hon. Foreign Secretary.

Members are requested to nominate on or before May 13 next fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22.—An ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member; but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if—

(a) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.

(b) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(c) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the By-laws.

(d) The nomination form is not received before or upon the day appointed therefor.

(e) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. LONGSTAFF,
General Secretary

LONDON SECTION

At the meeting at Burlington House, on April 4, Dr. R. Lessing described the proceedings at the International Conference on Bituminous Coals which took place at Pittsburg in November last year. The attendance was over 1700, and the meetings were held during the mornings, afternoons and evenings of the four days from November 15 to 18, inclusive. The aim of the Conference, which was organised by Dr. S. Baker, President of the Carnegie Institute of Technology at Pittsburg, was said to be to take stock of existing knowledge of practical fuel technology, to acquaint workers on the other side of the Atlantic with the work done in Europe in this branch of research, and to stimulate research in the coal problem in America. A brief outline of many of the 43 papers which were submitted was given, and the general conclusion to be drawn from them seemed to be that the trend of present-day thought in fuel matters shows a distinct bias towards the conversion of coal into oil and the use of solid fuel in powdered form. It was curious that such a state of affairs should exist in America, where so much petroleum oil is produced, but this fact was accounted for by Dr. Lessing in the enormous increase of motor traffic and the need for finding new sources of oil fuel. The Conference was an unqualified success, and Dr. Lessing added that the general tenor of the contributions to the proceedings gave weight to the opinion that we are on the threshold of a new era in the utilisation of coal, and the possibility foreshadowed of refining the natural product, of concentrating its intrinsic value, and of applying it in novel ways, is changing our conception of its potentialities and making us realise that we are witnessing the beginning of a revolution in the application of our principal store of energy. The problem of coal utilisation, he said, is becoming an international one, and not merely a national one. Special attention was called to papers on the Bergius, the Fischer, and the Patart systems for the production of liquid fuels from coal, and the possibility of the combination of such processes with ordinary gasworks was pointed out as being the most likely course of development on practical lines.

In the discussion, after Dr. Dyvorkowitch had mentioned the fact that he himself had read a paper in the Chemical Society's rooms 34 years ago, when he referred to the production of oils by high-pressure processes and generally had called attention to the need for more scientific study of coal, Mr. P. C. Pope expressed regret that only one paper had been read at the Pittsburg Conference dealing with the subject of inorganic matter in coal, and that by Dr. Lessing himself. If we could bring the ash down to 0.5% we should considerably improve combustion conditions in boiler and other furnaces. Although we had given greater attention in this country than had been the case in America to the cleaning of coal, we had not paid anything like sufficient attention to the matter. There had been no real research in this country to get down to the real fine art of cleaning coal, and people were too much inclined to be satisfied with anything from 5 to 20% of ash. That ought to be reduced to 1% or even 0.5%, and the cost of so doing would be repaid in the additional worth per calorie in oil or gas.

Dr. Lessing made a brief reply, in which he spoke

of the possibilities of the various processes now being evolved for the production of oil from coal, pointing out that preparations are being made for testing some of these systems on a large practical scale.

CALENDAR OF FORTHCOMING EVENTS

Apr. 22 FARADAY SOCIETY. *Oxford Meeting*. University [and 23. Museum, Oxford. (See issue of April 15, p. 340.)

Apr. 25. INSTITUTION OF MECHANICAL ENGINEERS. *Graduates' Section*, London. Storey's Gate, St. James's Park, S.W.1, at 7 p.m. "Parcel and package conveying plant," by H. W. Cadman.

Apr. 25. SOCIETY OF CHEMICAL INDUSTRY. *Chemical Engineering Group*. Additional Meeting at the American Film Co., Ltd., 89-91, Wardour Street, London, W.1, at 8 p.m. "Permanent moulding machines for cast iron," by Prof. J. W. Hinchley, illustrated by a film showing the process. Informal dinner at 6.30 p.m., at the Restaurant Au Petit Riche, 44, Old Compton Street, W.1.

Apr. 25. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2, at 8 p.m. (Cantor Lecture I). "The measurement of light," by J. W. T. Walsh. (Also on May 2.)

Apr. 26. ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, 35, Russell Square, W.C.1, at 7 p.m. (1) "A contribution to the theory and practice of the carboprocess" by C. Lighton. (2) "Thiocarbamide as an impurity in thiocyanates," by Dr. T. Slater Price and J. W. Glassett. (3) "Note on the performance of the B.P.R.A. photo-electric density meter," by J. O. C. Vick.

Apr. 26. INSTITUTE OF BREWING, *Scottish Section*, Caledonian Station Hotel, Edinburgh. "Some notes on water drilling practice and refrigeration as applied to the sinking of shafts." By A. D. Brydon.

Apr. 27. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2, at 8 p.m. "Fire waste (loss of property by fire) and its effects on the economies of national life in Great Britain." By G. E. Keay.

Apr. 27. SOCIETY OF GLASS TECHNOLOGY. Tenth Annual General Meeting in Sheffield. At 1 p.m., luncheon at the King's Head Hotel, Change Alley, High Street, Sheffield. At 2.30 p.m. The annual General Meeting. Short discussion on the proposed Glass Convention. At 3 p.m. Ordinary General Meeting at the University, St. George's Square, Sheffield. General discussion on furnace efficiency, introduced by "A brief review of furnace developments," by Prof. W. E. S. Turner.

Apr. 27. INSTITUTE OF CHEMISTRY, *London Section*, 30, Russell Square, W.C.1, at 8 p.m. "Some recent legislation affecting chemists," G. Stubbs.

Apr. 27. INSTITUTE OF CHEMISTRY, *Belfast and District Section*. Visit to Belfast Electric Power Station.

May 6. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual General Meeting. Imperial College of Science and Technology, Kensington, S.W.7. Formal business meeting at 6 p.m. An informal dinner will probably be held at 6.30 p.m., and at about 8 p.m. a paper entitled "Chemical fire extinguishers" will be read by Dr. W. R. Ormandy.

CHEMICAL SOCIETY

At a meeting held on April 7 the President, Prof. H. Brereton Baker, C.B.E., F.R.S., announced the personnel of the Committees for the year 1927-1928; the Research Fund Committee will meet early in June, and applications for grants must be received by June 1. The Faraday Lecture, entitled "Problems and Methods in Enzyme Research," will be delivered by Prof. Richard Willstätter at the Royal Institution on Wednesday, May 18, at 5.30 p.m., admission being by ticket only.

Prof. Willstätter was elected by ballot as an Honorary Fellow of the Society

Dr. H. King discussed:—

Trypanocidal Action and Chemical Constitution. Part VI. Amphoterie s-Carbamidoarsinic acids.

SOME s-carbamidoarsinic acids with a free basic centre have been prepared and examined for trypanocidal activity. A study has also been made in continuation of work done in Part IV of the nitration of *o* aminophenol derivatives. The results obtained, together with those of Reverdin, are consistent and show that the relative orienting powers in *o*- and *p* aminophenols are in the order $\text{OH} > \text{NHAc} > \text{OAc}$.

Prof. C. K. Ingold said that the anomalous orienting activity of the free hydroxyl group was due to the production by ionisation of the powerfully orienting negative pole O^- , which promotes rapid substitution through the ion, even although very little of it is present at any moment. Soper and Smith's experiments on the chlorination of phenol were illuminating in this connexion. The speaker asked whether Dr. King had observed a diminution in the activity of the hydroxyl group relatively to that of the competing group when the conditions were made less favourable to ionisation: if ionisation could be completely prevented the series should be NMeAc , $\text{NHAc} > \text{OMe}$, $\text{OH} > \text{OAc}$. Prof. Ingold believed that all the observations which had previously been held to support the theory that oxygen supersedes nitrogen in the *op*-orienting series involved the substitution of free phenols under conditions in which they could ionise.

Prof. R. Robinson remarked that he had already drawn attention to the unique position of hydroxyl in the series OR, but the view that a significant concentration of phenoxide ions can exist in a strongly acid solution could hardly be maintained. It was more probable that the high directive power of OH relative to OR is due to *potential* ionisation; i.e., a mechanism is provided in the former case for the ready expulsion of a proton in the course of chemical change. Thus a higher proportion of tentative unions between the substituting agent and the aromatic compound became fruitful.

Dr. King replied that experiments to elucidate Prof. Ingold's point had not been performed.

Mr. E. J. B. Willey discussed:—

Active Nitrogen Part III. Active nitrogen and the metals.

In Parts I and II experiments were described in which it was shown, on the assumption that the active nitrogen

content of a gas mixture could be evaluated by means of the reaction $N'_2 + 2NO \rightarrow 2N_2 + O_2$, that the energy content of active nitrogen was of the order of 2.0 volts. By passing active nitrogen over thin metallic spirals of various metals, it is shown that the metals vary in their powers of effecting the catalytic decomposition of active nitrogen. This variation is attributed to the difference in the stability of the nitrides of the metals. Copper is active at the ordinary temperature, platinum and zinc at somewhat elevated temperatures. The nitrides of molybdenum and tungsten are too stable to effect catalytic decomposition of active nitrogen even at high temperatures. From the rise in temperature of the spirals for different flow speeds of active nitrogen the energy content of the latter has been determined, and shown to agree with the values obtained previously, viz., 2 volts.

In reply to Dr. N. V. Sidgwick, the author agreed that the results depended on the validity of the reaction between active nitrogen and nitric oxide, but said that another method, depending on the formation of iron nitride in the iron-nitrogen arc, was available.

Dr. H. E. Watson described:

Esterification in mixed Solvents. [With B. V. Blude] THE velocity constants for suberic and *n*-butyric acids in mixtures of isoamyl alcohol with benzene and petroleum have been measured using hydrochloric acid as catalyst; Goldschmidt and Udby's formula $(r - a) \log a/(a - r) = r = Kt$ gives satisfactory values. These constants increase very considerably with increase in the proportion of inert solvent, the values for 90% benzene and petroleum rising in a hyperbolic manner to approximately 14 and 20 times the values in the pure alcohol.

It is suggested that the velocity depends not on the concentration of catalyst in the whole solution, but on the ratio of catalyst to alcohol molecules. If this were so, the velocity constant for a 90% solution would be 10 times that calculated in the ordinary way. The additional rise observed is qualitatively explained by the relative increase in velocity which occurs on increasing the concentration of catalyst.

The results show that reaction can take place readily when very few ions are present in the solution.

An observed decrease in velocity constant for small additions of inert solvent and certain minima in the conductivity values have not yet been explained.

Dr. R. H. Pickard asked whether ordinary amyl alcohol, containing a constituent which readily reacts with hydrochloric acid, was employed.

Dr. Watson replied that the amyl alcohol did not react appreciably with hydrochloric acid in 48 hrs., the experiments lasted only 6-7 hrs.

Prof. F. L. Pyman discussed:-

The Alkaloids of Ipecacuanha. Part IV. [With W. H. Brindley.]

It is shown that the formula given below, which has been developed from a suggestion made by Prof. Robert Robinson, F.R.S., on phytochemical grounds, is in accord with the known properties of emetine, and enables

intelligible formulæ to be deduced for the subsidiary alkaloids of ipecacuanha.

Mr. F. H. Carr having spoken in congratulatory terms, Prof. R. Robinson said that Prof. Pyman and Mr. Carr had greatly overestimated the importance of the part which he had played in this development. Analogies now suggested that the constitution of lycovine (narcissine) may require modification in the sense of the emetine formula. Thus instead of the normal C_6 chain lycovine may contain a branched chain as in the formula

or in the related δ -lactone.

SOCIETY OF PUBLIC ANALYSTS

An ordinary meeting was held at the Chemical Society's Rooms, Burlington House, on April 6, Mr. John White, Vice-President, being in the Chair.

Certificates were read for the first time in favour of Messrs. F. C. Bullock, B.Sc., T. H. Fairbrother, M.Sc., R. S. Rack, and S. G. Sherman.

Certificates were read for the second time in favour of Messrs. A. G. J. Lipscomb, B.Sc., W. L. Matthews, S. J. Rogers, B.Sc., E. F. Waterhouse, H. W. Webb, A. S. Wood, M.Sc., Ph.D.

The following were elected Members of the Society:- W. G. Carey, F.I.C., W. F. Elvidge, B.Sc., L. S. Fraser, B.Sc., A.R.C.Sc., F. P. Hornby, B.Sc., G. R. Lynch, O.B.E., M.B., B.S., D.P.H., E. C. Martin, and G. G. Philip.

The following papers were read and discussed:-

"The sequence of strokes in writing," by C. Ainsworth Mitchell, M.A., and T. J. Ward.-Systematic experiments have been made to determine to what extent one may trust to the appearance of one of two intersecting lines being uppermost, as a proof that it was made more recently than the other. It is shown that the appearance coincides with the fact in the case of insoluble opaque pigments such as lead pencil, but is deceptive when a transparent pigment, such as an aniline dye, is in question. The relative position of lines made with writing inks which undergo oxidation, and thus form an opaque

insoluble pigment, can usually be accurately determined, but if the ink has been blotted the observation is, as a rule, untrustworthy.

"Observations on the washing of gluten from flour," by D. W. Kent-Jones, Ph.D., and C. W. Herd, B.Sc.—It is shown that the use of a special washing solution, such as that suggested by Dill and Alsberg, does not eliminate the errors inherent in gluten determinations. Even when the same amount of washing water is used and the same procedure followed, personal differences in the manipulation of the dough and gluten cause large variations in the result. It has been found, however, that each operator gets essentially consistent results, which means that the ratio between the nitrogen of the flour and the dried gluten is approximately constant for each worker.

"A numerical expression for the colour of flour," by D. W. Kent-Jones, Ph.D., B.Sc., and C. W. Herd, B.Sc.—The colour of flour may be expressed by the tints given to two distinct solvents. The yellow colouring matter is extracted by means of petroleum spirit, and its colour is measured in a special form of colorimeter. This figure indicates the natural whiteness, or alternatively, the artificial bleaching of the flour. The grade of the flour may be judged by the amount of the reddish-brown pigment present which, presumably, comes from the finely-powdered offal present. This pigment is determined in the colorimeter after extraction with alkaline methyl alcohol.

"The determination of free mercury in commercial products," by H. B. Dunncliff, M.A., Sc.D., and Kishen Lal, M.Sc.—The main constituents of the substance containing free mercury are removed by extraction with a suitable solvent. The residue is treated with bromine water, the resulting mercuric bromide is dissolved in alcohol, and the mercury is precipitated as mercuric sulphide, which is filtered off and weighed in a Gooch crucible. The method is shown to give accurate results with various commercial products, such as mercury ointment, grey powder and mercury fulminate.

BRITISH ASSOCIATION OF CHEMISTS

The annual meeting of the Manchester Section was held at the Exchange Hotel, Manchester, on March 30. Mr. E. N. Marchant, in his chairman's address, surveyed the activities of the Association during the past year, giving instances in which the Association had been able to obtain legal or other redress for its members which members had been unable to secure by personal action. It was highly important that members should realise the assistance the Association was able to afford in legal and other matters, and that they should not hesitate to seek the advice of its officers in any difficulty confronting them. After reviewing the reasons underlying the recent modifications in the Unemployment Benefit Fund, Mr. Marchant referred to progress in the matter of registration. Membership of the Section had increased from 220 to 250 in the course of the year.

A vote of thanks to the Chairman for his address was proposed by Mr. W. E. Kay and seconded by Mr. F. Scholefield. Mr. R. Brightman proposed, Mr. F. S. Choate seconded, a vote of thanks to the Hon. Secretary, Hon. Treasurer and members of the retiring Committee. Mr. E. N. Marchant, Mr. T. O. Morgan and Mr. P.

Chorley were re-elected Chairman, Hon. Secretary and Hon. Treasurer respectively. The meeting was preceded by a hot-pot supper, and the evening concluded with musical items.

PHYSICAL SOCIETY

At the meeting on April 8, Dr. E. Griffiths described and exhibited an instrument for determining the carbon dioxide content of a mixture of air and carbon dioxide based on the measurement of the velocity of sound in the mixture. Essentially the instrument is a compact and portable modification of Kundt's tube. The vibrating source consists of a quartz crystal set into vibration electrically as a piezo electric resonator. The frequency of vibration of the crystal is about 40,000 per sec., and as in the familiar Kundt's tube experiment the vibrations are reflected from a disc carried by a micrometer screw. The quartz crystal is placed in contact with a pair of electrodes, one of which is connected with the plate and the other with the grid of a thermionic valve, as shown in the figure. When the

reflector is at such a distance that it corresponds to a node of the stationary train of waves set up in the chamber containing the oscillating crystal, the reaction of the reflected wave on the crystal produces a sharply defined peak in the anode current, which is indicated by the milliammeter inserted in the circuit. The distances between successive nodes can thus be readily determined, and after suitable calibration of the instrument with mixtures of known composition, the results can be interpreted in terms of the CO_2 content of the mixture. An accuracy of about 2% is claimed for the method, but in the ensuing discussion it was shown how this limit of accuracy could be much improved upon by using the whole train of stationary waves set up.

B. L. Worsnop read a paper on "The scattering of X-rays and the 'J'-phenomenon." The J-phenomenon was first observed and described by Prof. C. G. Barkla. Essentially, the evidence for the existence of the J-phenomenon consists in the discontinuities observed in the scattering of X-rays by a light atom as the penetration of the incident radiation is progressively increased. The author, using a modification of Barkla's experimental method, designed to reveal directly the discontinuities, if present, failed to detect any evidence whatever of the reality of the phenomenon. Dr. E. A. Owen, in the ensuing discussion, remarked that, experimenting with a wedge of scattering material, he had found no discontinuity in the intensity of the radiation transmitted by progressively increasing thicknesses of the wedge—a result indicating the absence of the J-phenomenon.

Prof. C. L. Fortescue read a paper on "The characteristics of thermionic rectifiers."

CORRESPONDENCE

MERCURY IN COAL TAR

SIR.—In your issue of April 8 a paragraph appears on the above topic. It is of special interest to persons engaged in the carbonising industries, as quite likely most workers have at some time or other found mercury in their tar.

The amount found by Mr. Kirby corresponds very closely to the concentration found in a tar tank dealt with recently. This is not altogether surprising, as the tank contained 7 tons of tar, and the mercury which entered from a broken thermometer weighed approximately 1 grm. This gives a result tolerably close to one part in seven millions.

It does not appear at all strange that Dr. Aston found that the groups of isotopic lines were indistinguishable from those of ordinary mercury.

Thermometers inserted in gas, liquor and tar mains sometimes break. The bulb and mercury find their way into the pipe. This constitutes a possible source of origin of mercury in coal tar.

"FREE CARBON"

PERSONAL AND OTHER ITEMS

The late Mr. H. E. Nichols, a director of the Anglo-Persian Oil Co., Ltd., Scottish Oils, Ltd., and other oil companies, left £33,030, with net personalty of £28,213.

The late Mr. E. J. Woolley, chairman of James Woolley, Sons & Co., Ltd., manufacturing chemists, Manchester, left £167,173, with net personalty £158,419.

Preservatives in Food

The Minister of Health has issued an Order amending the Public Health (Preservatives etc. in Food) Regulations. It states that the following proviso shall be inserted at the end of Article 4 (1) and at the end of Article 11 (1): "The provisions of this Article shall not apply so as to prohibit the presence of sulphur dioxide in any article of food other than meat if it is shown either (a) that the article, not being an article specified in Part II of the said Schedule, is intended to be used in the preparation of an article which is so specified or (b) that the article, being itself an article so specified, other than fruit or fruit pulp, is intended to be so treated before it is sold or exposed for sale by retail, so as to comply with the provisions of the Schedule as regards the proportion of sulphur dioxide contained."

It is also stated that, in the first line of proviso (a) to Article 1 the words "manufacture for sale or" shall be inserted after the words "prohibit the."

Mineral Oil Refining in Great Britain

The growth of this industry in Great Britain in recent years is indicated by the figures of imports of crude petroleum for refining, which rose from 1 million gall. in 1913, 7½ million gall. in 1919, and 4 million gall. in 1920 to 10½ million gall. in 1921, and increased steadily to 569 million gall. in 1925, falling back slightly to 539 million gall. in 1926. Approximately 1½% of the world's production of crude petroleum in 1926 was refined in Great Britain, the chief sources of the supplies

of imports being Persia (419 million gall., compared with 381 in 1925), Venezuela (64 million gall., compared with 151 in 1925), Mexico (38 million gall., against 27 in 1925), Colombia (7½ million gall.), and the United States (5½ million gall.). British countries (Trinidad and Sarawak) contributed a little over 2 million gall. Apart from oil included in the Customs Returns as crude, certain other kinds of imported petroleum, mainly kerosene, from Rumania and Russia, were treated by refining or cracking. The total output of liquid products from the refineries in Great Britain (including cracking plants, the output of which, however, is relatively small) is returned by the companies concerned as 554 million gall., in addition to certain quantities of asphalt, pitch and wax. These products were derived from distilling (and, to a small extent, cracking) 576 million gall. of petroleum, of which, approximately, 80% was crude oil, and about 15% was semi-refined oil, and 5% was kerosene; together with 40 million gall. of oil and naphtha obtained by retorting Scottish shale. In 1925 the total output of liquid products amounted to 605 million gall. Of the 677 million gall. of motor spirit (petrol) retained in Great Britain and Northern Ireland in 1926 for consumption or replenishing stocks, 133 million gall. (or 20%) was manufactured in this country, the corresponding figure for 1925 being 487 million gall., retained, of which 26% was manufactured in this country. As regards kerosene, 204 million gall. was retained in 1926, of which 18% was of home manufacture (as against corresponding figures of 165 million gall., and 33% in 1925). Of fuel oil 359 million gall. was retained and 253 million gall. shipped for the use of steamers engaged in the foreign trade, and of this total of 612 million gall., 35% was home produced (the corresponding proportion in 1925 being 42%).

New British Chemical Standard Cast Iron "D2"

The organisers of the British Chemical Standard movement announce that they now have ready a grey phosphoric cast iron in the form of very fine turnings, and having the following standardised compositions:—

Silicon	1.31%
Phosphorus	1.07%
Manganese	1.64%

The approximate composition of the elements is graphitic carbon 2.5%, combined carbon 0.8%, sulphur 0.03%.

This iron takes the place of iron "D" as regards phosphorus content, but also fulfils the need for a low silicon iron and a high manganese pig iron standard. Used in conjunction with Hematite Iron "A" this covers the range of most irons met with by the foundry chemist. As usual, it is packed in bottles containing 500, 100 and 50 grms. of fine turnings free from dust and may be obtained either from Organising Headquarters or most laboratory furnishers at a price which is estimated as sufficient to cover the cost.

The Centenary of the Friction Match

In *Nature* of April 2 will be found an interesting article by Prof. W. A. Bone, F.R.S., on the centenary of the friction match, in which he gives information about the nature and circumstances of this pioneer invention.

PARLIAMENTARY NEWS

Sugar-Beet Factories

In reply to Mr. Duckworth, Mr. Guinness said he understood that four new beet sugar factories would be erected this year, namely, at Bardney, Selby, King's Lynn, and Alscott. Of these, the Bardney factory only had received guarantees under the Trade Facilities Act. The Act expired on March 31 last.—April 4.

Safeguarding of Industries (Paper Industry)

Sir P. Cunliffe-Lister informed Mr. Smedley Crooke that duty was imposed on packing and wrapping paper, including tissue paper, exceeding 10 lb., but not exceeding 90 lb. per ream, on May 1, 1926. It was not possible to distinguish, for any period before that date, between the imports of paper which then became dutiable and those which still remained free of duty. Consequently, it was necessary to give figures throughout relating to the total imports of packing and wrapping paper, including tissue paper. The average declared value (c.i.f. British port) of this paper imported into the United Kingdom in 1925 was £1.21 per cwt.; in January–April, 1926, £1.19; in May to December, 1926, £1.15; in the whole year 1926, £1.17, and in January–February, 1927, £1.14. Apart from the inevitable increase in unemployment during the coal stoppage, the orders and employment were considerably better. April 5.

Artificial Silk Industry

In reply to Mr. Thurtle, Mr. McNeill said that the total amount of capital guaranteed by the State under the Trade Facilities Act to companies engaged in the artificial silk industry was £85,000; there was no reason to anticipate any loss. April 7.

British Industries Fair

In reply to Mr. Williams, Sir Burton Chadwick said that the loss on the series of British Industries Fairs from 1915 to 1927, was £9,500. Grants had also been provided from public funds in the last two years for publicity expenditure totalling £46,000. In 1902 the home buyers attending the exhibition were 49,000, whereas in 1926 they were 73,000.—April 11.

Cream Substitutes

Replying to Brigadier-General Clifton Brown, Sir K. Wood said it was not possible to make Regulations to stop the manufacture of cream from a cheap type of imported butter and milk powder, but the existing provisions of the Sale of Food and Drugs Acts would appear to be sufficient to prevent it being sold as cream. The prohibition of preservations would apply to the substitute as well as to cream, and he was advised that the keeping properties of the substitute might be expected to be less than those of genuine cream. April 11.

Safeguarding of Industries (Wrapping Paper)

Mr. McNeill informed Mr. A. V. Alexander that baked paper consisted of paper with a coating of varnish or other material, and that the body paper was usually of a dutiable description. In such cases duty was chargeable under Sub-section (2) of Section 11 of the Finance Act, 1926, on the value of the coated paper, as a whole, if within the limits of dutiable weight. April 12.

Safeguarding Duties

Mr. Churchill stated, in a written answer to Mr. Wardlaw-Milne, that the approximate amounts derived from the safeguarding duties on key industry goods, mantles for incandescent lighting, and packing or wrapping paper, from the date of imposition up to March 31, 1927, were £2,277,000, £15,000 and £495,000 respectively.—April 12.

COMPANY NEWS

BELL'S UNITED ASBESTOS CO., LTD.

The thirty-ninth annual meeting, held on April 7, was presided over by the chairman, Mr. J. Alfred Fisher. The past year had been an exceptionally trying one. Whilst there was a decline in their ordinary business with coal, iron and other companies, this was compensated for by greater activity in the building trade and a larger turnover in Poilite and Everite materials, and also by an increased demand for certain other goods. A larger return was also obtained from overseas business. With reference to the future, the outlook appeared to be a little more hopeful than it had been for a long time. The activity in the building trade seemed likely to continue, and this, together with an increasing demand for Everite roofing material—the value of which for factories, railway and dock buildings and similar works was widely recognised on account of its great strength and durability—should favourably affect Bell's Poilite and Everite Company. Also certain negotiations were in progress which, if completed, should lead to a material increase in the scope of their joint operations. It was not unreasonable to expect further considerable developments in the motor industry, which should be accompanied by an increasing demand for brake and clutch equipment manufactured at the company's asbestos factory at Harefield, solely for Raybestos-Belaco, Ltd., in which concern they held half the share capital.

For the accounts see CHEMISTRY AND INDUSTRY, April 1, 1927, p. 298.

TARMAC, LTD.

The report for 1926 shows a net result, after providing for general establishment charges and taking into account £2446 interest and dividends received from and providing for trading losses incurred by subsidiary undertakings, of a loss of £6202, to which must be added provision for income tax based on the average of the last three years £23,500, making a loss of £29,702. The balance of profit brought forward was £16,882, and £40,000 has been transferred from reserve account. After deducting the above loss, there remained a balance for disposal of £27,180. Dividend on preference shares for the half-year to June 30, 1926, absorbed £5500, and after writing off £18,124 for depreciation, and paying directors' fees at half the rate voted for 1925, £1806 remained to be carried forward. During the strike manufacturing conditions became increasingly difficult, and many of the company's works had to close down. Cost of production was also increased by the shortage of tar and coal and the high prices charged for them. The directors state that the demand for the company's manufactures continued to be satisfactory. Mr. Cecil Martin, one of the directors, has been appointed managing director, and Mr. C. E. Hickman has been appointed a director.

CENTRAL PROVINCES MANGANESE ORE CO., LTD.

The nineteenth ordinary annual general meeting, held on April 8, was presided over by the chairman, Mr. M. Wilkinson. Trading profits for 1926 amounted to £294,368, against £456,693 for 1925, the net profits being £246,176, against £347,054. Reserve received £19,197, compared with £100,000, and a final dividend of 15%, accompanied by a 5% bonus, was declared, making 30%, tax free, for the year, carrying forward £66,034. The reduced profits were accounted for by the exceptional difficulties occurring during the year. Owing to the coal strike, for upwards of seven months practically no ferro-manganese was made in this country, the Continental and American demand keeping the company going. The chairman referred to the arrangement made with the United Kingdom Ferro-Manganese Co., Ltd., for the unification of interests. The company is to supply manganese ore to the new company at an arranged price, and the ferro manganese makers who are concerned in the new company are to purchase all their ore requirements from the new company. The new company is to buy from the ferro-manganese makers the whole of their production of ferro-manganese at an arranged price, and to sell it for the benefit of the ferro-manganese makers and the Central Provinces Manganese Ore Co., Ltd. The capital of the United Kingdom Ferro-Manganese Co., Ltd., is £350,000, and the ferro-manganese makers concerned are the Darwen and Mostyn Iron Co., Ltd.; Dorman, Long and Co., Ltd.; United Steel Companies, Ltd.; and Wigan Coal and Iron Co., Ltd. The supply of manganese ore suitable for making ferro-manganese was a matter of concern to British steel makers, as the deposits in the Caucasus, at Niropol, and in West Africa and Brazil were not under British control, and the only other available supply of any importance was from India. The mines owned by the company were the most important in that country, so that the advantage to the British steel makers of having an adequate supply of high-grade ore at their command was obvious. By the arrangement the company had secured an outlet for a considerable portion of its production, and had consolidated its interests with a number of ferro-manganese makers who had taken supplies of its ore for many years past. The directors were of opinion that the production of ferro-manganese in this country was now on a sound and profitable basis.

BRANSTON ARTIFICIAL SILK CO., LTD.

An issue has been made of 1,000,000 ordinary shares of £1 each at par and 1,000,000 deferred shares of 4s. at 5s. each. The company has purchased a nucleus plant already producing artificial silk, which will be installed in the Branston factory. A contract has been let to John Hetherington & Sons to supply the necessary machinery to a value of £403,000. The board consists of the Marquess of Carisbrooke (chairman), who is associated with Lever Bros., Mr. C. T. Bazell, Mr. F. J. Farrell, Mr. J. Spence, Mr. H. E. Garle, and Sir Edmund Russborough Turton, M.P. The technical advisers are Dr. J. N. Goldsmith, the consulting chemist; Dr. A. Perl, managing director of Oscar Kohorn & Co., Vienna; and Mr. J. Swinburne, M.Inst.C.E., F.R.S., the

consulting engineer. The factory allows for expansion in working space for future extensions. The buildings as they stand, with certain adaptations and additions, will be sufficient for a daily production of 10 tons of artificial silk, and with other extensions the output could be raised to 16 tons per day.

BRITISH PORTLAND CEMENT MANUFACTURERS, LTD.

The total income for the year to December 31, 1926, including a refund of Excess Profits Duty, was £644,169, compared with £773,036 for 1925. A final dividend has been declared on the ordinary shares of 7½%, making 12½% for the year. To facilitate the improvement and extension of the company's manufacturing position, both at home and abroad, it was necessary to increase the capital from £2,800,000 to £4,000,000, and the required resolution was passed at the sixteenth ordinary general meeting held on March 19.

BABCOCK AND WILCOX, LTD.

After allowing for all expenses and taxation, the net profit for 1926 was £716,577, compared with £785,026 for 1925. Pension fund received £20,000, and reserve fund £150,000. A final dividend has been recommended of 8%, making 13%, tax free, for 1926, a similar dividend being paid in 1925, leaving £161,442 to be carried forward.

L. AND N. COAL DISTILLATION, LTD.

This company has been formed by a committee representative of the British heavy industries for the purpose of applying the L. and N. low-temperature coal-distillation process. The whole of the capital was privately subscribed.

UNITED MOLASSES CO., LTD.

The first annual general meeting of this company, which was registered in January, 1926, with a share capital of £1,000,000, took place on April 5, Mr. F. K. Kielberg, chairman and managing director, presiding. The business has shown steady progress since its inception in 1911 with the erection of a small tank installation at Hull of a capacity of 2800 tons. From this modest start had sprung a world-wide organisation with tank installations in all the most important sugar-producing countries, the total capacity to-day approaching 400,000 tons, or an increase of nearly 150,000 tons since January last year.

The profits amounted to £344,858 up to December 31, 1926. Depreciation absorbs £87,575, preliminary expenses £13,200, leaving net profits amounting to £244,083. General reserve received £30,000, a staff superannuation fund was started with £2500, and a dividend of 10%, less tax, was declared on the ordinary shares. After providing for the 8% dividend on the preference shares, the sum of £19,883 was carried forward.

The company had recently sold their entire holding of 90% in Crosfields Oil and Cake Co., Ltd., Liverpool, at a substantial profit, their sole reason for selling being that Crosfield's business unavoidably led them into competition with the company's most important buyers of molasses. Trading during the first three months of the current year had been satisfactory, and prospects for the remainder of the year were favourable.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4 ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Sal ammoniac.—£45—£50 per ton. Chloride of ammonia £37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate.—2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb., according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic, Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.

Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbanilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—1s. 10° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 4s.—4s. 3d. per gal., 60% O.P. Solvent, 4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 10s. per ton.

TAR PRODUCTS

Acid Carbolic.—Crystals, 8½d.—9d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 6d.—2s. 8d. per gal. Steady. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 2s.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 9½d. to 2s. 2d. per gal. Firm. Pure, 2s. 1d.—2s. 4d. per gal.
 Xylol.—2s. 1d.—2s. 6d. per gal. Pure, 3s. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 10d.—1s. 11d. per gal. Solvent 95/160, 1s. 7d.—1s. 8d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £8 per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals, £11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—75s.—85s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—9s. 6d.—13s. per gal. Nominal. 90/180.—5s. per gal. Heavy.—6s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4).—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.
 Aniline Salts.—7d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4d. per lb. Fair enquiry.
 m-Cresol 98/100%.—2s. 8½d. per lb. Only limited enquiry.
 p-Cresol 32/34° C.—2s. 8½d. per lb. Only limited enquiry.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—2s. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£81 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d. — 1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb. ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb. Firm and brisk.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s. 3d. per oz.; 500 oz. lots—1s. per oz.
 Acid, Boric B.P. Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 5½d. per lb. Less 5%. Firm.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 3½d. 1s. 4½d. per lb. Technical 11½d.—1s. per lb. Both in good demand.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 2½d. per lb. Less 5%. Firm market.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 6d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzophenanthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d. 14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuth B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.
 Bromides.—Ammonium.—2s. 4d.—2s. 6d. per lb. Potassium.—1s. 11d.—2s. 1d. per lb. Sodium.—2s. 2d.—2d. 4d. per lb. All spot.
 Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ether meth.—1s. 1d.—1s. 11½d. per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 5d. per gal. f.o.r. makers' works, naked.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb., for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron. Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—22s. per cwt., 112 lb. lots.
 Magnesium Carbonate.—Light Commercial £33 per ton net.
 Magnesium Oxide.—Light Commercial £67 10s. per ton, less 2½%; Heavy Commercial £22 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol. A.B.R. recryst., B.P., 18s. 9d. per lb. net. Synthetic, 11s.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb. Detached cryst., 14s. 6d. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig., 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonat.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin.—3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar) 96s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17s. 2d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb. Very limited enquiry.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C. 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s. per cwt. net. Crystals, 5s. per cwt. extra.
 Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
 Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
 Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
 Sulphonol.—7s. 6d. per lb.
 Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.
 Thymol, Puriss.—11s. 6d.—12s. per lb., according to quantity.
 Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
 Aubepine (*ex Anethole*).—10s. 6d. per lb.
 Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.
 Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
 Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb.
 Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.
 Cinnamic Aldehyde.—Natural, 17s. per lb.
 Coumarin.—10s. 6d. per lb.
 Citronellol.—14s. 6d. per lb.
 Citral.—8s. 3d. per lb.
 Ethyl Cinnamate.—10s. per lb.
 Ethyl Phthalate.—3s. per lb.
 Eugenol.—9s. 6d. per lb. Geraniol (Palmarosa). 17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.
 Methyl Anthranilate.—8s. 6d. per lb.
 Methyl Benzoate.—4s. 6d. per lb.
 Musk Ketone.—35s. per lb.
 Musk Xylol.—8s. 6d. per lb.
 Nerolin.—3s. 9d. per lb.
 Phenyl Ethyl Acetate.—12s. per lb.
 Phenyl Ethyl Alcohol.—10s. 6d. per lb.
 Rhodinol.—27s. 6d. per lb. Safral.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb. Good demand.

ESSENTIAL OILS

Almond.—11s. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—12s. per lb.
 Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 3d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure.—6s. per lb.
 Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—10s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 18s. 9d. per lb. Japanese, 8s. 6d. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than June 11th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court,ancery Lane, London, W.C.2, on April 28th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

Applications.

Akt. Separator. Centrifugal separators. 9349. Apr. weden, 24.4.26.)
 Ashcroft. 9603. See X.
 Blackett. 9724. See X.

British Separators, Ltd., and Cahill. Centrifugal separating apparatus. 9628. Apr. 7.
 Cooper, Henshaw, and Holmes & Co. Drying gases. 9618. Apr. 7.
 Hall, and Reckitt & Sons. Rotary drum etc. filters. 9630. Apr. 7.
 Howe. Furnaces. 9237. Apr. 4. (U.S., 5,426.)
 Hughes, and Synthetic Ammonia and Nitrates, Ltd. Carrying out chemical reactions. 9421. Apr. 6.
 Knupffer. Furnaces. 9296. Apr. 5.
 Poverud and Sonsthagen. Apparatus for mixing, degassing, etc. viscid materials. 9442. Apr. 6.
 Priest. Kilns or furnaces. 9242. Apr. 4.
 Proctor. Furnaces. 9775. Apr. 9.
 Smith. Wet treatment of subdivided materials. 9374. Apr. 5.

I.—Complete Specifications

23,555 (1925) and 8400 (1926). Davidson. See X.
 58 (1926). Baker Perkins, Ltd., Baker, Prescott, and Soc. Anon. Anc. Etabl. Savy, Jeanjean, et Cie. Apparatus for concentrating and evaporating liquids such as syrups. (268,437.)
 218 (1926). Benson. Mixing-machines. (268,447.)
 5409 (1926). Haddan (Akt. Ljungströms Angturbin). Furnaces. (268,578.)
 15,385 (1926). Evershed & Vignoles, Ltd., and Perry. See XXXIII.
 15,590 (1926). Johnson (I.-G. Farbenind.). Heating granular materials. (268,599.)
 21,786 (1926). Scherbaum. Centrifugal grinding-mills. (257,917.)
 22,260 (1926). Ges. für Lande's Eismaschinen. Separating from gas mixtures the readily condensable constituents. (258,856.)
 23,960 (1926). Burn and Lancaster. Rotary mixing machines. (268,658.)
 29,529 (1926). France. See X.
 32,922 (1926). Dunsmore. Hydro-extractors or centrifugal machines. (268,701.)
 2753 (1927). Weidmann and Littel. Fire-extinguishing compositions. (268,711.)
 *26,661 (26,746 (1926). Soc. L'Air Liquide. Carrying out exothermic chemical reactions. (268,721—2.)
 *9237 (1927). Howe. Furnaces. (268,834.)

II.—Applications

American Hydrocarbon Co. Apparatus for extracting vaporisable matter from fragmentary solid materials etc. 9282. Apr. 5. (U.S., 4,526.)
 Billen and Enders. Apparatus for manufacture of charcoal. 9767. Apr. 9.
 Haddan (Stettiner Chamotte A.-G.). Distilling ovens etc. 9831. Apr. 9.
 I.-G. Farbenind. Production of liquid hydrocarbons. 9196. Apr. 4. (Ger., 14,426.)
 Johnson (I.-G. Farbenind.). Treatment of montan wax. 9716. Apr. 8. Production of products from montan wax. 9717. Apr. 8.
 Laing and Nielsen. Manufacture of illuminating etc. gases. 9523. Apr. 6.
 Namml. Vennoot. Silica en Ovenbouw Mij. Coke ovens. 9216 and 9606. Apr. 4 and 7. (Ger., 3,426, and Holland, 7,426.)
 Nyrop. Manufacture of oil products. 9250. Apr. 4.
 Reynard and Tapping. Binding material for finely-divided fuels etc. 9191. Briquetting finely-divided coal etc. 9192. Apr. 4.
 Salerni. Treatment of hydrocarbon gases etc. 9520. Apr. 6.
 White (Internat. Bitumenoil Corp.). Retorts. 9393. Apr. 5.

II.—Complete Specifications

24,183 (1925) and 16,265 (1926). Sutcliffe. Distillation of coal etc. (268,080.)

32,999 (1925). Holmes & Co., Ltd., Parker, and Henshaw.

Drying of fuel gases. (268,429.)

60 (1926). Daniels. Ovens for distilling coal and the like. (245,764.)

8604 (1926). Robinson and Parkes. *See* III.

12,071 (1926). I.-G. Farbenind. Manufacture of liquid fuels. (252,018.)

17,761 (1926). Pamart. Apparatus for carbonising combustibles at low temperatures. (268,613.)

21,748 (1926). James (Brown Instrument Co.). Gas analysis apparatus. (268,637.)

*23,527 (1926). Geipert. Testing samples of coal by distillation. (268,718.)

*27,947 (1926). Allgem. Ges. für Chem. Ind. Liberating hydrocarbons. (268,726.)

*6800 (1927). Bamat-Megum A.-G., and Heller. Low-temperature distillation. (268,745.)

*8476 (1927). I.-G. Farbenind. *See* III.

*8890 (1927). I.-G. Farbenind. Conversion of hydrocarbons of high boiling-point into compounds of lower boiling-point. (268,796.)

*8983 (1927). Mallery. Utilising residue oils containing water. (268,814.)

*9216 (1927). Nauml. Vemoots. Silica en Ovenbouw My. Coke ovens. (268,832.)

III.—Complete Specifications

8604 (1926). Robinson and Parkes. Resolution of emulsions or suspensions containing tar or oil. (268,547.)

*8476 (1927). I. G. Farbenind. Production of conversion products of tars, mineral oils, and the like. (268,774.)

IV.—Applications

British Dyestuffs Corp., Ltd., Bunbury, Shepherdson, and Tatum. Production of anthraquinone intermediate. 9388. Apr. 5.

I.-G. Farbenind. Manufacture of vat dyestuffs. 9471. Apr. 6. (Ger., 18.11.26.) Production of dyestuffs containing chromium. 9197. Apr. 4. (Ger., 15.4.26.)

Manufacture of benzanthrones. 9214. Apr. 4. (Ger., 3.4.26.)

IV.—Complete Specifications

7663 (1926). Brit. Dyestuffs Corp., Ltd., and Tatum. Anthraquinone dyestuffs. (268,542.)

25,315 (1926). Bensa. Manufacture of dinitro products of perylene and its halogen derivatives. (260,568.)

*7439 (1927). I.-G. Farbenind. Metallic compounds of *o*-hydroxy-azo dyestuffs. (268,754.)

*8771 (1927). I. G. Farbenind. Manufacture of diazotised amines of the cyclic series. (268,789.)

*8931 (1927). I.-G. Farbenind. Manufacture of azo-dyestuffs. (268,807.)

*9214 (1927). I.-G. Farbenind. Manufacture of benzanthrones. (268,830.)

V.—Applications

British Celanese, Ltd. Manufacture of artificial silk etc. 9175. Apr. 4. Manufacture of cellulose derivatives etc. 9684—6. Apr. 8. (U.S., 14 and 16.4.26.)

Carpmuel (I.-G. Farbenind.). Production of dycings. 9526. Apr. 6.

Draper. Spinning artificial yarns etc. 9277. Apr. 5.

Johnson (I.-G. Farbenind.). Production of coloured cellulose. 9715. Apr. 8.

Mallabar. Manufacture of cellulose acetate. 9418. Apr. 6.

Soc. Chimique des Usines du Rhône. Continuous manufacture of cellulose acetate. 9500. Apr. 6. (Fr., 26.7.26.)

Welch. Manufacture of artificial silk etc. 9175. Apr. 4.

V.—Complete Specifications

514 (1926). Courtaulds, Ltd., Glover, and Topham. Production of artificial silk. (268,455.)

4048 (1926). Harrison. Manufacture of wool-like cellulosic material. (268,505.)

9535 (1926). Courtaulds, Ltd., Glover, and Diamond. Manufacture of cellulose derivatives. (268,552.)

*3832 (1927). Comptoir des Textiles Artificiels, and Chavassieu. Manufacture of artificial textile threads, fibres, etc. (268,734.)

*8495 (1927). Verein f. Chem. Ind. *See* VII.

*8658 (1927). Deutsche Zellstoff-Textilwerke. Treating artificial silk made from viscose. (268,783.)

VI.—Applications

British Celanese, Ltd. Treatment of yarn packages with liquids. 9683. Apr. 8. (U.S., 12.4.26.)

Heberlein & Co. Producing pattern effects on goods made of artificial fibres. 9215. Apr. 4. (Ger., 3.4.26.)

IV.—Complete Specifications

32,912 (1925). Chem. Works (Sandoz). Increasing the affinity of animal fibres for dyestuffs. (245,759.)

*8623 (1927). Heberlein & Co. Producing pattern effects on textiles. (268,781.)

*9215 (1927). Heberlein & Co. Producing pattern effects on goods made of artificial fibres. (268,831.)

VII.—Applications

Jacobsson. Dissolving aluminiferous raw materials. 9227. Apr. 4. (Sweden, 6.4.26.)

Mond (I.-G. Farbenind.). Production of anhydrous chlorides free from oxides. 9494. Apr. 6.

Storer and Taylor. Manufacture of red oxide of iron. 9769. Apr. 9.

VII. Complete Specifications

32,508 (1925). Deutsche Gold- und Silber-Scheideanstalt, and Andrich. Production of concentrated solutions of alkali cyanides. (268,420.)

3592 (1926). Azogeno Soc. Anon., and Toniolo. Manufacture of ammonium nitrate. (247,227.)

3593 (1926). Azogeno Soc. Anon., and Toniolo. Rapid evaporation of ammonium nitrate solutions. (247,228.)

15,584 (1926). Comp. de Prod. Chim. et Electro-Metallurgiques Alais, Froges, et Carmargue. Manufacture of anhydrous magnesium chloride. (255,042.)

23,200 (1926). I.-G. Farbenind. Regeneration of catalysts used in the production of phosphorus pentoxide or phosphoric acid. (259,201.)

*8254 (1927). Andreas. *See* IX.

*8405 (1927). Verein f. Chem. Ind. Recovery of acetic acid from solutions of acetyl cellulose. (268,778.)

*8607 (1927). Lichtenberger and Kaiser. Manufacturing pure white barium and calcium sulphate. (268,779.)

*8783 (1927). Goldschmidt. *See* XVIII.

*9035 (1927). I.-G. Farbenind. Manufacture of alkali bisulphate. (268,817.)

VIII.—Complete Specifications

33,009 (1925). United Glass Bottle Manuf., Ltd., and Moorshead. Glass furnaces. (268,432.)

*8609 (1927.) Brit. Thomson-Houston Co., Ltd. Producing silica articles. (268,780.)

IX.—Applications

Chem. Fabr. Grunau, Landshoff & Meyer, and Kirchner. Accelerating setting of hydraulic binding-agents. 9354. Apr. 5.

Doughty. Producing coloured cement etc. 9783. Apr. 9.

Johnson (I.-G. Farbenind.). Production of plasters etc. 9818. Apr. 9.

IX.—Complete Specifications

30,613 (1925). Levy. Bituminous emulsions. (268,411.)

*4110 (1927). Eckel. Cement. (268,736.)

*8254 (1927). Andreas. Burning of cement, lime, etc. (268,767.)

X.—Applications

Ashcroft. Separation etc. of minerals etc. 9603. Apr. 7.
 Blackett. Separating minerals of different densities. 9724. Apr. 8.

Dehn (Thompson Products, Inc.). Alloy steel. 9712. Apr. 8.

Deutsche Versuchsanstalt für Luftfahrt. Manufacture of aluminium. 9514. Apr. 6. (Ger., 2.12.26.) Aluminium alloys. 9515. Apr. 6. (Ger., 27.12.26.)

General Electric Co., Ltd., and Smithells. Manufacture of alloys of nickel and chromium. 9590. Apr. 7.

Gustafsson. Producing metals from oxide ores. 9441. Apr. 6. (Sweden, 10.4.26.)

King, Morris, Schiff, and Wilder. Mineral-concentrating apparatus. 9508. Apr. 6. Treatment of ores etc. 9509, 9511 and 9512. Apr. 6. Extraction of tin from ores. 9510. Apr. 6.

Remy and Roitzheim. Extraction of zinc. 9470. Apr. 6.
 Smith. Treatment of ores etc. 9362. Apr. 5.

X.—Complete Specifications

23,555 (1925) and 8400 (1926). Davidson. Separation of minerals and other substances. (268,043.)

653 (1926). Poldihütte. Steel alloys. (245,792.)

12,019 (1926). Corneliuss. Producing iron and other metals and alloys having a very low percentage of carbon. (252,017.)

17,878 (1926). Krupp Grusonwerk. Production of zinc. (255,482.)

18,528 (1926). Vegesack. Manufacture of steel. (268,616.)

23,319 (1926). Metallbank und Metallurgische Ges. Copper-aluminium alloys. (268,654.)

29,529 (1926). France. Washing minerals by means of liquid streams. (268,682.)

*32,173 (1926). Krupp. Making steel insensible to the action of hot gases and vapours. (268,730.)

*4512 (1927). Jessup. Electrolytic production of metals, in particular, magnesium. (268,738.)

*4511 (1927). Jessup. Manufacture of magnesium. (268,737.)

*5949 (1927). Denumer. Annealing metal articles. (268,740.)

*8354 (1927). I.-G. Farbenind. Fining iron. (268,770.)

*8864 (1927). Aumund. Blast furnaces. (268,793.)

*8900 (1927). Oelberger. Copper-tin-nickel alloy. (268,798.)

*9021 (1927). Allgemeine Elektrizitäts-Ges. Production of metallic coatings upon non-conducting oxides. (268,815.)

XI.—Applications

Crossley. Primary cells. 9200. Apr. 4. Secondary cells. 9201. Apr. 4.

Goeddertz. Production of lead accumulator batteries. 9333. Apr. 5.

Lobley and Wiggin & Co. Electric furnaces etc. 9670—7. Apr. 8.

Siemens-Elektrowärme-Ges. Insulating-stone for electric furnaces. 9360. Apr. 5. (Ger., 6.4.26.)

Williams. 9682. See XIV.

XI.—Complete Specifications

32,918 (1925). Noeggerath. High-pressure system for electrolytic processes. (268,426.)

26,456 (1926). Hagsphl. Electrodes for electric accumulators. (265,918.)

*22,994 (1926). Kodak, Ltd. Electrical deposition of organic materials. (268,717.)

*4512 (1927). Jessup. See X.

*9147 (1927). Fromont. Electric accumulators. (268,828.)

Imray (Kirkham and Raymond). Manufacture of alkaline earth and magnesium salts of eugenol etc. 9535. Apr. 6.

Rheinische Kampfer-Fabr. Production of inactive menthol. 9230. Apr. 4. (Ger., 15.2.27.)

Silur Techn. and Chem. Produkte Ges., and Thorn. Condensation products. 9829. Apr. 9.

XX.—Complete Specifications

24,366 (1925) and 5058 (1926). Pollak. Treatment of condensation products of carbamide or its derivatives with formaldehyde. (240,840 and 266,389.)

*30,219 (1926). U.S. Industrial Alcohol Co. See XVIII.

*7111 (1927). Commercial Solvents Corp. See XVIII.

*8744 (1927). I.-G. Farbenind. Manufacture of decomposition products of organic compounds. (268,775.)

XXII.—Application

Du Pont, Du Pont, and U.S.F. Powder Co. Explosives. 9617. Apr. 7.

XXIII.—Complete Specifications

15,385 (1926). Evershed & Vignoles, Ltd., and Perry. Apparatus for the detection and estimation of impurities and dissolved matter in water and other fluids. (268,597.)

19,986 (1926). Jalowetz. Treating waters for brewing. (261,708.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Weldless steel pipes (A.X. 4553). *British India*: Chemical and pharmaceutical products (366). Tinplate (A.X. 4555); Hematite iron pig (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *British West Indies*: Fertilisers (367). *Bulgaria*: Galvanised iron wire (A. 4536). *Burma*: Perfumery, patent medicines (373). *Canada*: Tiles, brass, galvanised fittings, lamps (372). black steel pipe (A.X. 4518); black iron pipe (A.X. 4550). *Ceylon*: Perfumery, patent medicines (373). *Czechoslovakia*: Vegetable and animal fats and oils (377). *Germany*: Shellac, mercury (379); leather (380); bitumen (382). *India*: Perfumery, patent medicines (373). *Malaya*: Perfumery, patent medicines (373). *New Zealand*: Iron, non-ferrous metal rods and tubes, hollow-ware, oils, paint, pigments, varnish, steel, india-rubber goods, glass, lamps, leather, crockery, glassware, tinware (C.X. 2262).

News from Advertisements

A special course of eight lectures upon high-pressure gas research is again announced by the Imperial College of Science and Technology, London (page viii).

Applications are invited for the post of chief chemist to an important woollen firm (p. viii).

A chemist is wanted for practical inorganic and physical chemical research (p. viii).

A New "S.R.A." Colour

British Celanese Limited announce a new addition to their range of "S.R.A." colours for celanese, namely, "S.R.A." Blue VII. The characteristics of this colour are good solubility and yield, greenness of shade this being the greenest blue dyestuff of the "S.R.A." range

—and good all-round fastness properties. Whilst it is not recommended for guaranteed fadeless work, it is, nevertheless, of a high standard in resistance to light, whilst its fastness to acids, alkalis, soaping, ironing, cross dyeing, etc. conform well to the high standards of the remainder of the "S.R.A." range of colours. Further, it does not redden at all in artificial light, a property which makes it very valuable for the production of all types of mode and general shades in which retention of the daylight shade is desirable for artificial light. It is of particular use for the production of navy blues by mixture with other "S.R.A." colours on account of its good yield. For the highest yield this colour is best dissolved in hot soft water instead of in soap solution, which retards the dyeing somewhat. Where mixing with other S.R.A. colours for compound shades they also should be dissolved in a similar manner.

SERIES

LONDON, APRIL 29, 1927

EDITORIAL

Canada

CANADA is as near to us in Great Britain now as Edinburgh was to London three hundred years ago, and there is a far greater community of interest and affection. Personally, it is our misfortune that we have spent only a few hours in that great Dominion, a bright sunny day in November eight years ago; we saw nothing of her great cities, but shall remember how we sat by the shore of a secluded lake and saw the vivid autumn foliage, beautiful beyond conception, the calm waters, and a bright little chipmunk darting about in a tree. That is all we know of Canada at first hand, but like all the rest of us here we have many other links with that country. We have, as all of us, many friends and near relations who have visited Canada and know it well, several friends and near relations who live there permanently. It is this bond which keeps Canada so fresh in our minds, so near to us. We love the country, not for the spoils it gives, great and rich as these are, but because the Canadians are ourselves. True there is a great French population there, but this also, in many ways, and especially now, is very close to us. The Canadians have many advantages over us; the people who settled originally in that country, grown green with many trackless years, were the sturdier and bolder of men and women; there is a smaller proportion there of the froth and also of the dregs. So it happens that when we meet Canadians in Britain they are not only ourselves, but the best of us. Canada is no longer a mere pastoral country; it is amazingly rich in minerals and ores, in water power, in salt deposits of various kinds, in raw materials generally. It has great forests, harbours, railways, cities and towns; it has all our modern civilization without the *débris* which accumulates after a few centuries of careless and unprovident existence. We cannot, therefore, expect anything else than a well-established and flourishing chemical industry in Canada. Canadian scientific education and research is of no second-rate character; it attains to the highest level. When we consider the achievements of Canadian pure chemistry during the last ten or twelve years we think of several instances of genius which cannot be excelled in this or any other country. The chemical industry in Canada was naturally slow in growth, but was already becoming of importance at the end of the nineteenth century; since then it has made very rapid progress. So far as the Society of Chemical Industry is concerned, the original Canadian Section was formed five and twenty years ago. In 1920 the Canadian Section was found to be so large and

covered so wide an area that three separate Canadian Sections were formed, those of Montreal, Ottawa, and Toronto. Shortly afterwards the Shawinigan Falls Section was formed, and somewhat later the British Columbia Section. The various Canadian Sections have organised their own overhead Council to take charge of those matters in which joint consideration is desirable. The Society of Chemical Industry has had problems and difficulties of its own to face during the lean years which followed the war. Parsimony has been forced upon it simultaneously with expansion: its parsimonious habits will continue a little longer, but they will become less and less necessary, and we may look forward to a time, continually getting nearer, when the Society can afford measures of expansion which will be of even greater service to its many members in many countries, not scattered over the world, as if they were small islands sprinkled out of a can, but forming huge continents and dominions all interested in advancing the knowledge of chemistry, in publishing the knowledge, and in applying it for the benefit of mankind. This is the ambition of the Society of Chemical Industry; in realising this ambition the Canadian Sections have rendered yeoman service.

Canada's Resources

Few, indeed, cannot but be familiar with the riches which Nature has lavished on Canada: abundance of developable water power, vast areas of forest land, a singularly fortunate array of valuable minerals, and a soil which yields products of an excellence with which the humblest in the land is kept in daily familiarity. Much as we may know about Canadian resources, but few of us can possess so close a knowledge of them that we can dispense with the need to broaden and deepen our information. It is, therefore, singularly happy that, in this issue, which is devoted to the chemical and allied industries of Canada, we are able to print a number of communications written by representative Canadian authorities who review the resources which the Dominion offers to chemical industry, and indicate the remarkable progress which it has made. We are also indebted to Mr. C. F. Cross, F.R.S., who has written on the Canadian pulp and paper industry. The history of the development of chemical industry in Canada makes a romantic story, but important as past developments have been, it is certain that the future holds within its lap still more romance, that kind of romance which always accompanies pioneer work, and is never entirely absent from the onward march of industry. To remind ourselves of the vast possibilities of the Dominion, we have to realise—no easy matter for those who dwell in

our own tight little, bright little island—the immense space of land, three and a half million square miles, 'twixt Atlantic and Pacific, and then we must remember that though the mineral industry takes third place amongst Canadian industries, yet, as Dr. Macintyre observes in his article, "the prospective mineral wealth of Canada is unknown, as a large area of the country is as yet uninvestigated." Even now Canada ranks as the world's largest producer of newsprint, of nickel, cobalt—every chemist knows the names of the districts of Sudbury and Cobalt—and, of course, asbestos. Then, again, we recall the pioneering development of hydro-electric power which forms the foundation upon which a great part of the industrial fabric has been built during the past twenty-five years. In the Shawinigan area alone nearly six hundred thousand horse-power is available, but already installations capable of producing four and a half million horse-power are working in Canada, and still some 28 million horse-power in "white coal" awaits the yoke of the turbine. It will give some idea of the importance of hydroelectric development in Canada if we quote, from an illustrated booklet published by the Shawinigan Water and Power Company, figures relating to the electrical power supplied by the company to various local industries. Thus the local pulp and paper industry consumes 125,000 h.p., the asbestos mines and factories consume 20,000 h.p., the Aluminium Co. of Canada uses 50,000 h.p. for the manufacture of aluminium; whilst its subsidiary, the Canada Carbide Co., utilises over 30,000 h.p. in the manufacture of carbide, part of which is converted into acetylene and used by another subsidiary, the Canadian Electro-Products Co., for the manufacture of acetaldehyde, acetic acid and other important industrial chemicals. Further, the Canadian Carborundum Co. operates electric furnaces consuming 12,000 h.p. for the manufacture of carborundum, aloxite, and ferro-silicon. Another factor in industrial development which should be considered in addition to this lavish wealth of water power is the coal of Canada, the deposits of which are estimated to represent about 16% of the total reserves of coal in the world. Indeed, the coalfields of Nova Scotia represent the only deposits of coal on the Atlantic Coast of America. An interesting document recently sent by the courtesy of the High Commissioner of Canada tells us that, in the seventeenth-century Journal of Admiral Hovenden Walker, it is recorded about Cape Breton that "The Island had always in time of peace been used in common both by the English and the French for loading coals, which are extraordinarily good here, and taken out of the cliffs with iron crow-bars only, and no other labour." The story of Canada's resources tempts us to go on and on, but the tale is told with an authority to which we have no claim by the special contributions in this issue. The resources are there, whether in power, whether in organic or inorganic materials, and the achievements which have been accomplished prove that the technical skill to utilise them is also at hand. We are proud of the prowess of the Dominion, and we are confident that in the future there will be still greater developments to excite our admiration.

The Honorary Treasurer

Mr. E. V. Evans having served the Society well and faithfully for several years, now finds that he can no longer spare the time which that responsible post requires, and he announces his forthcoming resignation, to the great regret of the Society, and especially the Council, and probably with some measure of regret on his own part. Men, especially able men, do not like to leave a difficult task to which they have devoted many years of anxious thought and acute judgment. We do not, naturally, propose to discuss the personality of Mr. Evans; those of us who have met him on holidays, have faced him at lawn-tennis, have retired beaten but still desirous of facing him, have heard him play sundry musical instruments, have watched him play Mark Hambourg at billiards, have sat opposite to him when he has raised our weak no-trump to three no-trumps, and observed his expression when our opponents gleefully doubled us, we know him as a man. Not that we ourselves are critical or skilful at card games; we usually play nursery bridge, *pons asinorum*, as it were, and inscribe on the card table: *post mortem nulla voluptas*. Mr. Peter Jackson, the famous cigar merchant, said that you knew no man unless you had drunk port with him and played poker with him. In this sense, and in this sense only, we do not know Mr. Evans. We think Christmas Eve or Christmas Day is the best time to see the real man, but we are not considering him personally, we are merely concerned with his work as Honorary Treasurer. We prefer to forget the occasions when he and older and even graver men have donned the paper caps extracted from crackers, and flown with insolence and wine, have indulged in some primitive type of community singing. Though unmelodious was the song, it was a hearty note and strong, as Sir Walter hath it. Even Apollo unbends the bow at times. Now when Mr. Evans was yet young as an honorary treasurer, just cutting his milk-teeth in a financial sense, he was faced with a considerable problem, a weekly journal with unknown possibilities and unknown expenses, to be edited by one who had never done a day's editing in his life. This prospect would have appalled many a man, and we think even Mr. Evans had his anxious moments during the first two or three years, but he kept a tight hand on the purse strings, never paid half-a-sovereign if half-a-crown would do, curbed the extravagances of the editor, steadily reduced the loss, made both ends meet, and, finally, last year showed an excess of income over expenditure amounting to a few hundred pounds. He and his colleagues on the Council made other arrangements last year for cutting down unnecessary expenditure, and now that Mr. Evans is ready to retire he can hand over to his successor a position in which the income of the Society should exceed the expenditure by a sum which in the course of a very few years will recoup the Society the whole of the loss—if you can call it loss—which the Society has made since the war. This is an achievement of which Mr. Evans and the Society may legitimately be proud. We congratulate Mr. Evans on sticking to the ship until he had steered it into smooth water. He has had a hard task and done it well; his successor ought to have an easier one.

THE DEVELOPMENT OF CHEMISTRY AND CHEMICAL INDUSTRY IN CANADA

By DR. A. E. MACINTYRE

It is opportune and eminently appropriate that the Society of Chemical Industry should devote, at this time, a special issue of the JOURNAL to Canadian chemistry and chemical industry. Some six years ago the Society sponsored the first general organisation of Canadian chemists, and has continued to support and extend its beneficent influence in promoting the welfare and advancement of chemists and chemical science. The annual conventions of Canadian chemists were developed, and have been largely maintained, through the efforts of the Canadian Sections.

It is the intention in this issue to convey, in a general way, the progress and position of chemical science in the Dominion. It is obvious that the contributions cannot be expected to give a full and adequate presentation of the development and extent of Canadian chemistry and its correlative industries; nevertheless sufficient will be offered to indicate some of the progress which has been achieved since confederation, and future opportunities and possibilities.

The diamond jubilee of the Dominion, which will be celebrated this year, indicates that it is a comparatively young country. If it be young in years, a mere stripling, it is strong in possessing great natural resources, which, if correctly conserved, developed and utilised, will entitle it to be classed as a land of unlimited possibilities.

In 1867 the most sanguine and imaginative of the fathers of confederation had but a very slight conception of the great undeveloped resources of the country, because advancements in science and technology in the past half century have made possible potential resources which were not conceivable sixty years ago.

Notwithstanding the dictum that youth must always look onward and upward, it might be of interest to review some features of the condition of Canadian chemistry and chemical and allied industries during the first decade of confederation, and their gradual development to their present status. Therefore the oracular admonition will be disregarded, and some reminiscences presented in the form of a retrospective epitome.

More than half a century ago the 3,600,000 square miles of Canada was populated by less than 3,500,000 people, whereas to-day the number is approximately 10,000,000. It was a country of magnificent distances extending 4000 miles from the Atlantic to the Pacific, and, at the time of confederation, there were not more than 2300 miles of steam railway, whereas at present there is a mileage of 40,000. These two features are quite sufficient to explain some of the differences in industrial conditions of the past and the present, because there existed, except in two instances, no interprovincial railway communication, an essential for reciprocal trade and commerce.

Prior to confederation the chief industrial activities were lumbering, agriculture, fishing, and wooden ship-building, with small accessory industries appertaining to them. In some respects the position of chemical industry, at this time, presented features which were not much in advance of those in Britain at the middle of the

eighteenth century. It is true there were gas-works in the larger and more important towns, some paint manufacturers grinding principally imported oils and pigments, white phosphorus matches on combs of wood, and a few other minor chemical industries, but in the majority of instances operations were conducted by primitive methods, such as the collection of hardwood ashes from the stoves of the homes, leaching them in barrels and evaporation into crude potash salts. Soap making was more or less, like the ash industry, a household matter. The export of the surplus potash to Britain became unprofitable through competition from the Stassfurt salts. About 1855 the manufacture of petroleum was commenced in New Brunswick by distillation from the so-called coal schists (oil shale), and later the richer oil-producing mineral albertite, but the advent and competition of oils from the Pennsylvanian fields soon made oil recovery unprofitable. For many years, in places more or less remote from ocean or railway transportation, where salt springs existed, the water derived from these was evaporated in open pans for the recovery of the salt, but the amount produced was insignificant in comparison with the demand, which was largely supplied from Britain and Turk's Island. The evolution of Canadian industry from what might be termed the household type to the factory, synchronised approximately with confederation, and, as will be observed, the growth was very gradual, the impetus of development coinciding with the beginning of the present century. Thus the Dominion of Canada practically commenced its official career without any important chemical industry. At this early stage in the history of Canada, instruction in chemistry was not, in general, of a very high standard. Practical instruction in chemical laboratories had not received general recognition, and graduates desirous of fuller knowledge studied in Europe. Some of the larger universities had a chair of chemistry, but in the smaller institutions the instructor was, in many instances, also lecturer upon physics, general biology, geology, mineralogy, and on occasions some branch of theology, occupying the pulpit on Sunday. These last-named conditions even existed for thirty years after confederation at some institutions of learning. The analytical chemists in Canada were chiefly attached to the geological surveys or mines, being engaged in the analysis of minerals.

The influence of the extension of railway communication brought about interprovincial intercourse, and about 1880 there followed the establishment of a few chemical and allied industries. Some of these early enterprises ended disastrously. The demand for chemists, and interest in chemistry, was stimulated by the passing of legislation upon food adulteration, and the appointment of at least one Dominion (public) analyst in each province, and further augmented by the establishment of an experimental farm, with chemists employed upon the staff. About the same period the larger universities instituted and devoted more attention to instruction in practical chemistry. Simultaneous with these movements, chemical and allied industries developed, and analytical and consulting chemists were to be found in the larger cities, where they engaged in commercial analytical practice.

The spectacular development of Canada has occurred within the past thirty years, and the progress made is attributable, in no small degree, to its agricultural development. In fact, the general impulse in industrial evolution was contemporaneous with the settling of the agricultural territory of the middle west, which opened up new markets to the manufacturer and promoted railway construction. This stimulus almost coincided with the formation of the first Canadian section of the Society of Chemical Industry. It is unnecessary to describe in detail the advancement of Canada, as the data presented will be sufficiently illustrative of the growth of chemical industry and concurrently the demand for chemists.

The war had a pronounced influence upon Canadian industry. The demands made upon it changed, in many respects, the whole trend of management. Better factory equipment, greater mechanical efficiency, improved methods of manufacture and systems of cost accountancy, stricter attention to economic operation, labour-saving devices necessitated by reason of the scarcity and high price of labour, and other features which had been neglected or were not previously attainable. Just as in some other countries the great public awakening to the importance of chemistry to industry came with the requirements of the Great War, not only in regard to munitions, but also to other necessities. Only those familiar with the situation at the time can appreciate the imperfect conception which even influential and prominent industrialists possessed of resources available in Canada to assist the Allies in the great struggle, and the distrust and scepticism expressed of the ability of the Canadian chemist and engineer to cope with the new problems and difficulties which would arise. Technical men were faced with conditions which were more or less foreign to them. It is true that much of the information required, in the early stages, was available in Canada, both in respect to manufacture and inspection, and as the war progressed information, which was invaluable to Canadian scientists, was forthcoming from British sources. Nevertheless, the burden of working out the most rapid and efficient methods, the application of appliances and materials to unusual products, requirements for control in manufacture and inspection then fell upon the shoulders of Canadian chemists, metallurgists and associated technicians. Though difficulties were encountered, these, in time, were successfully overcome, and Canadian technical men maintained the reputation of their country as ably and nobly as did the men who served in France.

Reference to several achievements by chemists in Canada during the war may not be out of place in this recital of Canadian industry. How little did the Canadian chemists who attended the International Congress of Applied Chemistry in New York in 1912, and listened to the memorable address of W. H. Perkin, Jr., on "Rubber and its synthesis," wherein reference was made to the Fernbach-Mathews fermentation of starch with production of butyl alcohol and acetone, imagine that within five years a modification of this process would be successfully developed and operated in Toronto, on a large scale, producing thousands of gallons of Perkin's by-product—acetone employed in the manufacture

of cordite for small arm and artillery ammunition. Another instance was the equally successful synthetic production, on a large scale, of acetone from calcium carbide by processes evolved by the chemists of the Canadian Electro-Products Co., Ltd., at Shawinigan Falls, P.Q. The production of acetone was discontinued at the termination of the war, but the manufacture, commercially, of acetaldehyde, acetic acid, acetic anhydride, butyl alcohol, and the acetic esters of butyl and ethyl alcohol has been further developed. The electrochemical production of 99.9 % metallic zinc from the complex and refractory lead-zinc ores of the Kootenay district of Southern British Columbia, at the plant of the Consolidated Mining and Smelting Co., Ltd., Trail, B.C., was another achievement worthy of mention.

The dependency of agriculture upon chemistry, and the application of the latter to all branches of it and its products, is very generally recognized. There are those who openly maintain, and probably rightly, that agriculture "will never develop to its fullest extent until it is regarded as a chemical industry." Husbandry, when properly conducted and maintained, is a permanent source of wealth. It has already been stated that the great transition period in Canadian industrial development occurred about a quarter of a century ago, and for the purpose of comparative progress it may be pointed out that in 1901 the total value of agricultural products was \$362,000,000, whereas in 1925 the value was \$1,700,000,000.

The miner is dependent upon chemical industry for his explosives—the most important tool which he employs. The chemist takes a commanding position in the entire process of the recovery of the metal from the ore to the finished product. The prospective mineral wealth of Canada is unknown, as a large area of the country is, as yet, uninvestigated. The mineral industry takes third place among those of the country. Canada is the world's largest producer of nickel, cobalt and asbestos with, respectively, 80%, 85% and 94% of these substances, and it ranks third in silver and fourth in gold. The mine and its products give employment to a large number of chemists. A very good conception of the development of the mineral industry is obtained from the following data of values: 1886, \$10,221,255; 1901, \$65,797,911; 1926, \$242,855,000.

An influential factor of recent years in the industrial development of this country has been the partial utilization of the potential energy available from water power. A complete survey of the country has not yet been made, but so far as determined the power, at minimum flow, is estimated at 18,255,000 h.p. The capital invested in all plants using "white coal" for the production of power in 1891 was approximately \$4,000,000, whereas in 1926 it was \$840,000,000. The water power installation in 1926 was capable, normally, of producing 4,556,000 h.p. The present year will witness the completion of further large increases amounting to hundreds of thousands of horse power. A considerable portion of this power is utilised by chemical industries, such as pulp, paper, cyanamide, carbide, cyanide, phosphorus, aluminium, electro-metallurgical products and mining.

A small paper industry existed in Canada in pre-confederation days. It is only within the past thirty

years that the pulp and paper industry has assumed great importance. In 1925 the value was \$193,092,937. Canada to-day is the world's largest producer of newsprint. The production in 1910 was 215,000 tons, and in 1926 it had increased to 1,881,737 tons, which will be greatly exceeded when a number of large mills, under construction, commence operating this year.

The foregoing are a few general examples illustrative of Canadian industrial expansion. With few exceptions the chemical and allied industries have exhibited the same progressive development. It is impossible to obtain reliable data regarding these industries for the years prior to the formation of the Dominion Bureau of Statistics in 1920, and even the returns issued by the Bureau as "Chemical Industries" do not include all industrial establishments properly coming within that category, as many are contained in other statistical groups, such as pulp and paper, starch, etc. The capital invested in 1925, in all chemical industries, in Canada, is estimated at considerably over \$1,000,000,000; employees number about 110,000; wages and salaries in the vicinity of \$115,000,000; cost of material used \$400,000,000; and value of products \$750,000,000. These figures would indicate that the chemical industries occupy an important position in the industrial life of Canada.

Brief reference has been made to chemical education in the immediate post-confederation period. The position to-day is quite different. Educational facilities and opportunities have greatly increased. There are some 22 universities having an approximate teaching staff of 3500, and an attendance of 25,000 regular students. The lands, buildings, equipment, and scientific instruments are valued at \$45,000,000. Chemistry occupies an important place in the curricula of these institutions, and the majority of the chemical buildings and equipment compares well with similar institutes in Europe and America. Canada, through its universities, offers every opportunity for a complete education in all branches of chemical science.

Besides the sections of the Society of Chemical Industry, which have played such an important part in the development of chemistry in Canada, there is a Canadian section of the Société de Chimie Industrielle de France, which is an active factor in the promotion of science in the province of Quebec. A number of smaller chemical associations exist. These are chiefly located in university cities, and frequently in connexion with the university, but include chemists who are not attached to it. These bodies are all doing their share in promoting the advancement of chemistry. In 1920 the Canadian Institute of Chemistry was formed. This is a professional association of chemists, incorporated by letters patent, and corresponding in position to that of the Institute of Chemistry of Great Britain and Ireland. The Institute has provincial sections in Ontario, Quebec, Manitoba and the Maritime Provinces, with local branches in several cities. The Association of Professional Chemists of the Province of Quebec was incorporated by the Legislature of that province last year, and has been organised. Its objects, in the main, are similar to those of the Canadian Institute of Chemistry.

The world-wide competition for trade has had its

influence upon the Canadian industrialist, who, eager to maintain his position at home and abroad, has not hesitated to employ scientific men, and, as a result, industries formerly not employing chemists have turned to them for assistance in controlling the quality of materials and operations involving chemical or correlative science. The importance of chemistry in trade and commerce has been recognised. These conditions have opened a larger field of activity for chemists, with a correspondingly greater demand.

In considering the future prospects and possibilities of chemical industry in Canada a survey and examination of the natural resources must be made, because these will be in the future even greater dominating factors than they have been in the past. The sources of most of the material utilised by the chemist are largely derived from agriculture, mines and forests. It has been pointed out that Canada might claim to be considered a land of unlimited possibilities provided its natural resources are properly conserved, developed and utilised. The past history of Canada's natural resources is not bright, being darkened by many pages of neglect, waste and destruction. Some twenty-five years ago these conditions attracted the attention of the Dominion government, which, being impressed with the necessity of immediate action to conserve the public domain, created a conservation commission which made a survey of the natural resources, and at the same time initiated measures for their conservation. This ultimately developed into the Natural Resources Intelligence Service and Water Power Branch, departments of the government which are doing excellent service in promoting and directing attention to the resources of the country, their possibilities, utilisation and proper conservation. Brief consideration will be given to these natural resources, so necessary to chemical industry.

The basic industry for many years to come will be agriculture. There exists already a broad foundation upon which it can be advantageously extended. H. Hibbert recently stated that "Canadian agriculture" "would never be developed to its fullest extent until it is regarded as a chemical industry." There is good ground for this contention. The creative chemist, by applied methods, can greatly enhance the value of the husbandman's product, and can also assist in increasing the productivity of his labour by supervision of his soil and supplying plant foods for his crops, which would improve not only the quality and increase quantity, but also resistance to disease and pests; supply means for eradication of insects and disease, and utilisation of by-products and such like. The art of true conservation has not been developed among the Canadian agriculturalists to an appreciable extent. The future of this great industry should be one of the responsibilities of Canadian chemists.

At confederation it was considered that Canada possessed unlimited forest resources, which would endure for many generations. They were believed to be inexhaustible, and their conservation did not attract attention. Much ruthless waste was perpetrated in forest operations, involving the loss of large quantities of invaluable growing raw material. These sins of

omission and commission are recognised to-day. There still exist immense areas of timber limits which are being operated, utilised and conserved in a measure far superior to that in the past. The forest is daily supplying the chemist with thousands of tons of raw material, and pulp and paper is one of the most important industries, yet only about 50% of the wood is being utilised by conversion into paper, and very much less than that figure when calculated on the tree basis. The salvage of this waste material is one of the perennial problems which confront chemists, and the Canadian chemist who develops an economic method for its utilisation will be a benefactor of his country and chemical industry. There is another problem which may be presented to the pulp and paper chemist at no very distant day, viz., either some other source of sulphur or an economic method, other than the sulphite process, for pulp making. There are possibilities of the replacement of elemental sulphur by certain sulphur compounds existing among the Canadian natural resources but in a large number of cases transportation and other difficulties might bar their application, and thus, except in special adjacent locations, their use would not become general. The life of this great chemical industry depends upon the conservation of the forests. It therefore behoves the chemist to do everything in his power to conserve them, and perpetuate an important industry.

Whilst the forest, by growth, can, in time, be reproduced, such is not the case in regard to certain of the mineral resources. Depletion is a prominent feature in the mining industry which must be considered in reviewing resources of this class. The position of the chemist in relation to this industry is to devise and develop economical methods of recovery, removing all the metal, and at the same time controlling all operations. The mineral resources of Canada are very large, and the reserve existing will serve the demands of chemical industry for many years.

Of great interest to chemical industry is the development of cheap water power, making possible cheap energy for utilisation in all departments of industry, particularly in the electrochemical industry. Canada has an abundance of power, available at points close to established water and rail transportation. Hydro-electric power already is an important feature of Canadian industry, and, as it is ever increasing, it may well become the most important factor in the future industrial development of the country.

From an examination and review of the available data upon the natural resources of the Dominion, it is quite evident there is an ample visible supply for many years, but nevertheless endeavour will be made to reduce the wastage to a minimum by improved or new methods in industry, thus increasing efficiency and the wealth of the country, and at the same time conserving the resources.

The future success of chemistry and chemical industry in Canada depends on the chemist himself. The chemist engaged in the onward march of industry must not work in watertight compartments. He must possess a broad creative outlook, capable of calling to his assistance all branches of chemistry, and co-operating with associates of the borderland sciences. It will not suffice merely to

revamp processes and materials made in other countries. He must have sufficient imagination, ability and ingenuity to create and develop new processes and products, as well as originate new methods for well-known commodities and discover new applications for both the old and new.

The daily press of Canada has recently devoted editorial comment on the co-operation existing between certain governmental departments of Great Britain and the United States in the solution of common scientific problems, pointing to the "mere waste of effort and money on the part of two governments to set up separate and independent establishments to investigate the same questions, when co-operation might easily bring earlier results at smaller costs," and showing that such co-operation in the past "has proven of value." It is true that in some Canadian departments there is an unofficial exchange of information, and a certain degree of co-operation, still it might well be extended and official co-operation recognised and developed. There are many chemical problems which are common to Canada and other parts of the Empire, and by co-operation their solution might be accomplished more expeditiously and at less cost. To a certain degree such collaboration existed during the war, proving to be very valuable to certain Canadian industries. Whilst the Society of Chemical Industry, through its publications, keeps the chemist informed on the advancement and progress of chemistry, still it might be possible for the Society, which is closely affiliated and federated with all branches of the science, to act as a clearing house for matters appertaining to chemistry, particularly applied chemistry, thereby becoming a medium for collaboration, and thus accomplishing a degree of co-operation not yet attained.

CANADA'S RESOURCES IN RELATION TO CHEMICAL INDUSTRIES

By G. G. OMMANNEY

The chemical industry has been defined as embracing those industrial activities concerned with the preparation of products from raw materials by the process or means of chemical change. Such a broad classification necessarily embraces a wide range of manufactures, and to an important extent the industrial possibilities either present or future of a country may be gauged by its resources of materials and the conditions which it can offer favourable to the economic support of chemical industries. Canada is fortunate in this respect, and having in view the tendencies of modern production to develop along the lines of chemical processes it may be said that, in many directions, no country to-day offers a better field for such developments.

Let us therefore consider briefly Canada's situation in this respect, though within the limits of a brief review it will not be possible to do more than touch on some general aspects of this wide subject.

Electrochemical processes are the foundation of many most important chemical industries. These usually require an abundant supply of cheap power. Geological conditions in Canada have combined with the geography of the country to create a combination

which places at our disposal the largest and cheapest supplies of hydro-electric power that the world can offer in reasonably close proximity to established centres of population, developed land and sea transportation and accessible markets. In the provinces of Ontario and Quebec vast drainage areas from high table lands tributary to watersheds whose rivers flow into great water ways such as the Ottawa and St. Lawrence or into the sea, usually reach these outlets through abrupt and considerable falls in elevation. Such conditions have created water powers at sites so suitably located for cheap development that for large blocks of power the capital charge per horse-power created has been the lowest in the world.

Usually these rivers and their tributaries either take their source from or flow through abundant and large

resource may be given. On the Saguenay River, which flows out of Lake St. John in the province of Quebec, into the St. Lawrence, two developments are now in hand, which will create 1,300,000 h.p. The chief use of this power will be by a plant for the manufacture of aluminium. In addition to the power development, there is involved the construction of a large plant for this product, the building of a railroad and the establishment of a new town all in a country up till now absolute wilderness. Bauxite—the principal raw material used in making aluminium—has not as yet been found in Canada, and must be imported, so the water-power situation gets the credit for bringing us this most important chemical industry.

Canada's mineral resources form an important contribution to its list of assets for chemical industries.

FIG. 1

General View of the Plant of the Canadian Electro-Products Co., Limited, Shawinigan Falls, Que.

lakes located in the uplands, thus providing a ready means to regulate flow at the power sites, which is further controlled by the vast forests covering the drainage areas.

Similar favourable conditions exist in the provinces of Manitoba, northern Saskatchewan, Alberta and British Columbia, though in the three latter provinces, as in the case of the maritime provinces, abundant supplies of coal supplement the industrial use of the water powers.

The general position may be summarized by the statement that of 32 million available horse-power which has been measured on rivers within reasonable transmission distance of settled areas, only some 4,500,000 h.p. has been developed to date.

Canada has, then, as a first asset for the type of industry under consideration these water powers. One concrete example of the immense value of this single

We may exclude from this topic metallurgy, though really this science embraces the recovery of metals by chemical means, and it might properly be claimed that Canada's known and probable reserves of ores of gold, silver, nickel, copper, zinc, lead and other minerals are the raw materials for chemical industries in this respect. But, in addition, we have other minerals in use or available for use more directly connected with the subject of this article.

It will be noted that in 1926 Canada produced over 16 million tons of coal, of which perhaps 30% came from the Maritime provinces of Nova Scotia and New Brunswick and the balance from Saskatchewan, Alberta and British Columbia. Much of this coal is of good coking quality, and its distillation may be made the basis of industries for the production of dyestuffs, tars and tar products, fertilisers, etc.

The production of petroleum in Canada, though not at present large (339,000 barrels in 1926), comes from Ontario and Alberta. In the latter province, as well as in other parts of the west, the search for commercial petroleum fields is being vigorously prosecuted. The great success recently encountered in the Turner Valley (south-west of Calgary, Alta), where several wells with heavy flows of gas carrying a high percentage of naphtha have been brought in, as well as other favourable features elsewhere, give rise to expectations of greatly increased production in the near future. The refining of petroleum yields products including light and heavy oils, paraffin waxes and other products used in many industries.

We have not yet touched on one of Canada's most important industries—that of the production of paper and pulp. Here it may be truly said is a vast chemical (and mechanical) enterprise whose foundation rests upon the basic resources of the country. The story of

An important raw material in this industry is limestone—both calcitic and dolomitic, and it is fortunate that adequate supplies of suitable material lie handy to the principal points of use.

Another Canadian resource which may yet assist this industry includes large deposits of pyrites ore which, in view of the present crude sulphur situation in the southern United States, may in the not distant future become the Canadian source of supply of this important element.

It is also interesting to note that the large deposits of sodium sulphate which occur in the form of dog lakes of crystalline Glauber's salts in the western province of Saskatchewan are now being successfully worked to yield natural salt cake needed by the sulphate pulp mills. Even the refractory linings of the furnaces of these mills are being largely supplied from Canadian soapstone deposits.

Old country readers not familiar with Canada can

FIG. 2.

the Canadian pulp and paper industry is a romance of commerce. The development has been as rapid as it has been amazing. The chief factors have been Canada's water power resources already referred to, her abundant water ways, and her great heritage of forests of spruce and other suitable woods, which, under proper management and conservation, will yield sufficient raw material for the needs of the industry and its probable expansions for as long as may be required.

Pulp and paper mills have been erected at suitable points throughout the country, particularly in Quebec, Ontario, the Maritime Provinces and British Columbia. Manitoba also has developments in hand.

In 1925 Canada produced 2,772,507 tons of wood pulp, 1,884,705 tons of newsprint and other paper, and the aggregate value of all the products of the industry was \$202,783,017.00.

We have in Canada to-day 69 mills making newsprint and other paper and 80 mills making pulp—including sulphite, sulphate and ground wood

scarcely visualise or credit the story of her pulp and paper industry. Towns, thriving centres of population and activity with every modern convenience that cheap electricity and up-to-date construction can give, have come into being with astonishing rapidity in the heart of wilderness countries. Such places as Grand'mere and Shawinigan in Quebec, and Iroquis Falls in Ontario are examples.

Intensive organisation in production and marketing, chemical, mechanical, and botanical research have gone hand-in-hand with the forward march of the industry. Transportation companies such as the Canadian Pacific Railway have played their part. Not minor factors have been the supply of contented and industrious labour, and the winter climate of Canada greatly facilitates the cutting and first movements of the pulp wood.

In a country with such wealth of forest resources as is possessed by Canada, wood naturally plays an important part in construction of all kinds, including houses. This condition gives rise to a very large demand for

paint, and the production of paint forms one of the major chemical industries. Here again Canada is not without the requisite resources. Iron oxides and paints from Quebec, Ontario, Alberta, and British Columbia are in use, and deposits in Nova Scotia are likely also to be developed. The manufacture of blanc fixe and other pigments from large deposits of titanium ores near Montreal, Quebec, is now projected, whilst barytes deposits in certain parts of the country, though not as yet producing, furnish an opportunity for making lithopone. Ores of zinc and lead extensively mined in British Columbia and Quebec also furnish pigment materials.

Besides their possible use in metallurgy, the chromite

spodumene, which are the ores of lithia—a material used in the glass industry in order to reduce the viscosity of the melted glass, more especially in the manufacture of lamp bulbs and also in special kinds of glass. Lithium compounds are also used in the extraction of aniline dyes from coal tars, in certain medicines, and in at least one type of storage battery. These deposits are now under development.

In this brief review we have not touched on many important matters connected with the subject which offer opportunities, present or future, for the manufacture of chemical products to meet the needs of this rapidly expanding Dominion.

FIG. 3

Photograph of Grand'mere by the Fairchild Aerial Survey Co. of Canada, Ltd.

ores of Quebec present possibilities for the manufacture of dyes and tanning. The cobalt ores from the district of that name in Ontario give the largest supplies of that famous pigment material in the world. It is also used in the enamelling, porcelain, coloured glass, and earthenware trades. The enamelling and pottery trades may, perhaps, be classed as chemical industries, and for these Canada contributes from her rich store-house of minerals one of the highest grade felspar on the American continent, as well as a variety of kinds of clay suitable for many uses.

Great interest has recently been aroused by the discovery in Manitoba of large deposits of lepidolite and

Agriculture is Canada's first and most important industry. Fertilisers are needed and in use in certain sections of the country or for certain crops. But the vast fertile plains of the West do not yet require artificial fertilisation, and it would be difficult to predict when, if ever, the need will become at all general. Still the fertiliser industry is becoming of importance, and, with an eye to the future, it is interesting to consider Canada's position in regard to the supply of the basic elements of plant food. Nitrogen we may yet obtain from the atmosphere by use of our hydro-electric power resources: Cyanamide is already manufactured at Niagara Falls; ammonium sulphate will supply it.

and it is already produced by distillation of our coals. Fish-refuse plants on the Atlantic and Pacific Coasts furnish both nitrogen and phosphorus, and more such plants can be developed. These offer an opportunity for the export market, as well as for domestic use. Potash and phosphate will probably continue to be imported, but it is important to note that Canada's felspathic rocks contain high percentages of the former, and the apatite rocks of Quebec have a higher phosphate content than is found in the deposits of southern United States. These latter have been used in the past, but are not at present worked. Kelp seaweed on the Pacific Coast has been used to supply potash.

Before concluding, two important industries should be mentioned—chlorine products from salt deposits, and a carbide industry with world markets using Canadian limestone and water power.

The list is far from complete. We would suggest that those interested should study the Canadian Government Statistics of production of minerals and raw materials. Combined with an intelligent appreciation of Canada's other assets, her water powers, her forests, her coals, her agriculture and some study of her imports, they suggest many opportunities for industrial developments along chemical lines which are worth investigation. The Development Branch of the Canadian Pacific Railway issues from its Montreal office very convenient and concise summaries on all these resources which are available to all who ask for them.

CANADA'S HEAVY CHEMICAL INDUSTRY

By S. J. COOK

Although Canada's total area is given as 3,797,123 square miles, the industrial section comprises only about 16% of this area; occupied farm lands represent approximately 6% of the Dominion, so that there remains only about 10% of the total on which there are established all the other entities which go to make domestic and commercial Canada. This 10% is spread out in a section 3000 miles long from east to west, having an average width of about 120 miles from north to south—a total area of 360,000 square miles.

Appreciation of these facts is necessary to a proper understanding of industrial conditions and developments in Canada. Settlement has proceeded from the Atlantic coast westward, and later along the Pacific coast, and inland.

In the great central plains agriculture is the leading industry; the farms there are very large: community centres are far apart, and factories are few. In Ontario and Quebec, and to a less extent in British Columbia and in the provinces of Nova Scotia, New Brunswick, and Prince Edward Island on the Atlantic seaboard, mixed farming on smaller farms has kept the people more closely together, and has encouraged the development of centres where industries have grown up to supply the immediate needs, and later to provide more fully for the requirements of those whose livelihood is derived from the factory and shop system. This theme might be pursued through all the phases of the developments characteristic of a new land, particularly one of such great length from east to west, and relative narrowness from

north to south, but perhaps sufficient has been said to give the reader who has not had the privilege of travelling in Canada some concept of the peculiarities of the country from a geographical point of view.

Heavy chemicals, in every land, find their market as raw materials in other industries; production, therefore, to save transportation costs, and thereby to keep prices at as low a level as possible, is usually carried on in close proximity to the locality in which most of the output can be sold. For this reason the heavy chemical industry in Canada is chiefly centred in the provinces of Ontario and Quebec, although, because of the cost of transportation over long distances, there are representative plants at strategic points across the Dominion from Nova Scotia on the east to British Columbia on the west.

Production of industrial chemicals, such as sulphuric, hydrochloric and nitric acids, caustic soda, salt cake, calcium carbide, cyanamide, phosphorus, and compressed gases such as oxygen, hydrogen, carbon dioxide and acetylene, is the most important of the chemical industries in Canada. In 1925 the 40 plants in this industrial group, representing a capital investment of \$35,656,528, furnished employment to 2,409 workers during the year, and converted \$12,843,256 worth of raw materials into finished products valued at \$27,183,395, an advance of more than a million dollars over the corresponding figure for 1924. Of the total output in 1925, acids, alkalis and salts amounted in value to \$25,396,782, and compressed gases were worth \$2,086,613.

Sulphuric acid was manufactured in 8 separate plants; 2 plants produced acid for the manufacture of ammonium sulphate as a by-product in connexion with the operation of by-product coke installations; 4 made sulphuric acid for commercial distribution; 1 plant in British Columbia made acid for use in metallurgical processes in the treatment of zinc ores, and 1 other company in that province made its own sulphuric for use in the manufacture of fertiliser. Hydrochloric acid was made in 3 plants, nitric acid in 2 different plants, and phosphoric acid in only 1 plant. Calcium carbide for sale was produced in 2 establishments, while 1 other plant made this commodity for its own use in the manufacture of cyanamide. Bleaching powder, soda ash, liquid chlorine, caustic soda, glacial acetic acid, acetaldehyde, paraldehyde, phosphorus, cyanamide and sodium cyanide were, in each case, the product of a single plant.

Output from the 20 heavy chemical plants in operation during 1925 reached a total value of \$25,396,782, and as raw materials cost \$12,472,687, the value added by manufacturing processes amounted to \$12,924,095. Capital employed stood at \$32,236,424, and employment was given to 2,084 persons, to whom £2,992,695 was paid in salaries and wages. The 20 plants were located as follows: 10 in Ontario, 6 in Quebec, 3 in British Columbia, and 1 in Nova Scotia.

Production of compressed gases in 1925 totalled \$2,086,613 in value as compared with \$2,051,448 in the preceding year. Capital employed amounted to 3.4 million dollars, employment was given to 325 persons, and expenditures in salaries and wages amounted to \$481,595. Of the 20 plants in operation, 2 were located

in Nova Scotia, 4 in Quebec, 8 in Ontario, 3 in Manitoba, 1 in Alberta, and 2 in British Columbia. Acetylene was made in 12 different plants, carbon dioxide in 6 plants, oxygen in 9 plants, and aqueous and anhydrous ammonia in 1 plant only.

In addition to the plants just enumerated there are 3 plants producing hydrogen for the hydrogenation of oils in their own works, and 1 other plant extracting nitrogen from the air for the manufacture of cyanamide. Oxygen is obtained as a by-product at each of these plants.

Electrochemical products, including carbide, cyanide, cyanamide, artificial abrasives and artificial graphite, phosphorus, caustic soda, bleaching powder and chlorine, are produced in large quantities at various points in Canada, where hydro-electric power is cheap. Data compiled from various sources indicate that the investment in electrochemical plants in Canada is in the neighbourhood of \$35,000,000, whilst the value of products from these plants reaches a total of about \$40,000,000 annually. Development of hydro-electric power in large volume and at a low distribution cost has been followed by the building of plants to use electrochemical processes, and the output of such products has added appreciably to the value and volume of Canada's export trade.

In this connexion, interest in recent development centres in work being done at Arvida in the Lake St. John area, Quebec, where an enormous sum of money is being spent for the construction of hydro-electric power plants and for the building of a smelter to produce metallic aluminium from bauxite ore, imported from the United States; it is proposed to bring ore from British Guiana, but this step has not yet been taken. Canada's magnificent endowment of water-power sites suitable for commercial development constitutes one of the great natural resources of the Dominion; progress in this field in recent years has merely pointed the way to the achievement of greater things, and the near future will see advances made in this field, which are not likely to be excelled in any part of the world. Electric steam generation is already an established feature in many localities; at least one of the pulp mills in the province of Quebec obtains all the heat required for the cooking processes throughout the plant from this source.

Niagara Falls, in Ontario, and Shawinigan Falls, in Quebec, are the pioneer centres in the utilisation of hydro-electric power for chemical purposes.

Cyanamide and cyanide production at Niagara Falls continues on a great scale, a large part of the output going into the export trade with various countries.

The work done at Shawinigan Falls, during the late war and since, is too well known to need any further description here; the manufacture of acetic acid, acetaldehyde, paraldehyde, and other products from acetylene generated from carbide made in an adjoining plant was, and is, one of the finest achievements in the history of chemical science in Canada.

Carbide, for acetylene gas lighting, has been made for many years at Shawinigan Falls, Quebec, and Welland, Ontario; some of the output is used in Canadian mines and other industries, but by far the greater part is exported.

Bleaching powder, chlorine and caustic soda, made by

the electrolysis of brine pumped from wells on the property at the Sandwich plant of the Canadian Salt Company, are being produced in greater quantities year by year; the story of the successes won in the development of the processes now in use is one of the most interesting in the annals of Canadian chemical history. An excellent description of this plant and its products appeared recently in *CHEMISTRY AND INDUSTRY*.

These achievements are but the forerunners of a series of accomplishments that will continue to direct the interest of the keen business minds in the scientific world to the innumerable opportunities that Canada affords to those who have the vision to foresee the immense possibilities of properly selected enterprises.

Interest in the manufacture of sulphuric acid in Canada was stimulated in 1925, when the Mond Nickel Company built a plant at Coniston, Ontario, where the company operates a nickel-copper smelter, for the manufacture of high-grade sulphuric acid from the Bessemer converter sulphur-bearing gases that, for years, had been allowed to burn to waste in the air, to the detriment of the neighbourhood. Operations at this plant proved so successful and profitable that the capacity of the plant was doubled towards the end of 1926, in an attempt to meet the demand for acid. Formerly all the sulphuric acid made in Canada was obtained by the treatment of pyrites or sulphur. In 1926 the production of sulphuric acid amounted to about 210,000,000 lb. of 66° B_e acid. Exports of this commodity to the United States have grown appreciably in the past three years; in 1926 about 50 million lb. found its way into the export trade.

The principal users of sulphuric acid in Canada, in order of their average requirements, are petroleum refineries using about 40%; by-product coking plants taking 15%; the explosives industry and the wire and wire goods industry, each of which buys about 12% of the supply; and various others, such as the manufacturers of fertilisers, the makers of electrical apparatus and supplies, etc.

Limitations in the matter of fuel supply in Central Canada have promoted a demand for the establishment of additional by-product coking plants; the by-products will contribute to Canada's output of ammonia, ammonium sulphate, and tar, and there may be other products recovered or produced in these new plants.

Ammonium sulphate to the extent of nearly 20,000 tons per annum is made in Canada as a by-product from the plants producing coke or gas as their principal product. It is not, therefore, truly a product of the "heavy chemical" industry as generally described. There are many other such examples of chemicals or chemical products made in other industries, as, for instance, the making of intermediates in the explosives industry, and in the manufacture of superphosphate for use as an ingredient in mixed fertilisers; other examples may be found in the preparation of paints and varnishes, soaps and pharmaceutical preparations.

Canada's heavy chemical industry has been built up primarily to supply the domestic market with those products that are not readily obtainable elsewhere, either because of the inconvenience involved in the handling of shipments over long distances or by reason of the greater costs thus incurred.

A feature in the development of the heavy chemical industry in Canada, and, indeed, in the application of chemical science in any branch of industry in the Dominion, that is often overlooked by the zealous exponent of conservation and efficiency, is that the natural limitations of the market, due to geographical conditions, sometimes makes it advisable to forego the high efficiencies so desired by chemists, in order to produce, at a reasonable cost, those commodities for which there is a profitable and ready market. Changing conditions, brought about by the advances in chemical knowledge, or by the growth of population and industries, necessitate more frequent adaptations of the industry to its environment in Canada than is ever the case in an older land where industrial and commercial changes are less pronounced.

As the country grows, factory enterprises gradually become more profitable, and as reserves are built up the means are provided to promote research, and to increase the efficiencies of plant operations. There is admittedly less need for saving in the earlier stages of a country's industrial life, when natural resources supply an abundance, and often an excess, of raw materials, than there is when limitation of supplies tends to advance prices and to restrict output. So it is that in many of Canada's industries efficiencies of operation may not compare favourably with those obtained in European plants; but when the need arises the initiative and resourcefulness of the operators of Canadian plants always prove equal to the task in hand, as the records of the industry show beyond question.

Canada's chemical industries as a whole contribute in no small measure to the diversification of Canadian manufactures, and add very appreciably to the volume of production each year. If the larger view of chemical industry be taken, and the definition expanded to include all industries using chemical processes, the field represents not less than one-fifth of the aggregate value of Canadian manufactures.

In 1925, the latest year for which complete data are at hand, concerns using chemical processes made products valued in the aggregate at \$655,000,000, the grand total value of all manufactures in Canada in that year was \$2,678,000,000. The 28 industries using chemical processes included upwards of 1400 plants in which 87,000 persons found employment and earned nearly \$110,000,000 during the year.

The heavy chemical industry, as considered in this article, is one of the 28 industries referred to above, and in point of production values is the most important industry in a group of 10 usually selected as the representative "chemical" industries in Canada. In order of production values, these 10 rank as follows: (1) Acids, alkalis, salts and compressed gases; (2) paints, pigments and varnishes; (3) soaps, washing compounds and toilet preparations; (4) medicinal and pharmaceutical preparations; (5) explosives, ammunition, fireworks and matches; (6) inks, dyes, and colours; (7) coal tar and its products; (8) wood distillates and extracts; (9) fertilizers; (10) a miscellaneous group of industries, making chemical products not specified under any of the foregoing headings.

Some of the more important "heavy chemicals" produced by the industries just mentioned are itemised

in the following table. In this case production data are drawn from the entire chemical group, and not only from the producers of "Acids, alkalis, salts and compressed gases," heretofore regarded as the "heavy chemical" industry. This explanation seems necessary, because of the statistics previously given regarding capital investment, employment, distribution of plants by provinces, etc., all of which referred only to the 20 producers of acids, alkalis and salts and to the 20 plants making compressed gases.

Production of certain chemicals in Canada, 1925

AGRICULTURAL CHEMISTRY IN CANADA

By FRANK T. SHUTT, M.A., D.Sc., F.I.C.

Dominion Chemist and Assistant Director Dominion Experimental Farms

The application of chemistry to the solution of Canadian agricultural problems may be said to date from the establishment of the Dominion Experimental Farm system by the Federal Government in 1886-'7, though for some years previous to this time a provincial agricultural college had been in existence in Ontario—a teaching institution which in recent years has enlarged and extended its sphere of usefulness by undertaking investigational work in agricultural science. To-day practically every province in the Dominion has its agricultural college, at which in addition to the teaching work, more or less attention is given to experiment and research in agricultural matters.

In referring more particularly to the chemical work of the Dominion Experimental Farm System, it may be said at the outset that side by side with purely investigational work, the Division of Chemistry has carried on, chiefly through correspondence, an educational and advisory service for the "man on the land." This is a phase of the Division's activities which has grown with the years and become increasingly popular. This "bureau of information" to which all may freely apply—correspondence with the Division not even requiring postage—now furnishes advice to many hundreds of farmers in every province of the Dominion. By letter, printed matter and to some degree by analytical work, it seeks to supply reliable information, based on the science of agricultural chemistry, on soils—their nature and treatment—fertilisers and manures—their composition and use—fodder crops and feeding stuffs—their nutritional value and economic use—farm water supplies, the nature and application of insecticides and fungicides, and so on. Indeed, many years of this service have shown that there are few matters on the farm which do not call, at one time or another, for chemical aid. It is generally conceded that this means of disseminating information,

based on the results of chemical research and practical in its nature, is playing an important part towards making Canadian farming a rational and profitable vocation.

INVESTIGATIONAL AND RESEARCH WORK

Constant effort is made to assist by experiment and investigatory chemical research work all phases of farming—grain growing, mixed farming, stock raising, dairying, orcharding, etc., and accordingly the Division finds a very wide and varied field for its labours. With this in mind, it will be readily understood that in the space allotted for this account it will be possible only briefly to outline the salient features of a few of the more important or prominent lines of investigation which have received the attention of the Division.

Soils.—Since the profitable pursuit of farming must depend in the first place on the fertility of the soil, naturally, much attention has been given to a study of Canadian soils, and more particularly to those of virgin areas and of districts newly opened up for settlement in the Western prairie provinces. Although mixed farming and dairying are now becoming important features in Western agriculture, grain growing has been, and undoubtedly will continue to be, the predominating phase in Manitoba, Saskatchewan and Alberta. Consequently, the influence of continuous grain growing on the plant food, and more particularly the nitrogen and humus content, has been studied. As an illustration of this work and its results, it was found that in a period of 38 years the loss of nitrogen from virgin soil was approximately 40%, of which roughly 17% was removed by crops and 23% by cultivating, including the practice of summer-fallowing. The main data are as follows:

Depletion of nitrogen, 1884-1922	
Virgin and cultivated soils—Indian Head, Sask.	
	Nitrogen per acre, to a depth of 8 in.
Virgin soil	1 lb. 8,580
Cultivated soil, 38 years (1884-1922)	5,180
Difference or loss, due to removal in crops and to cultural operations	3,400
Removed by grain crops	1,465
Difference or amount dissipated by fallowing and other cultural operations	1,935
	3,400

Parallel with this work, experiments extending over considerable periods have shown that the adoption of a rotation in which the growing of grasses and legumes was included serves to maintain the soil's nitrogen and humus. It was also evident that this practice tends to preserve good tilth and the moisture-holding capacity of the soil, and to arrest to a large degree the loss of valuable soil by drifting—an inevitable result in the semi-arid districts of the prairie provinces following the constant breaking up of the soil's fibre by cultivation and summer fallowing.

Further interesting and valuable data in this question of the nitrogen upkeep of soils are presented from a plot upon which the legume (clover) was dug in and re-sown every second season for a period of 10 years.

In connexion with investigatory work with soils and fertilisers in Eastern Canada (Ontario, Quebec, and the Maritime provinces), soil-fertility problems have been studied chiefly in connexion with long-cultivated and partially exhausted areas. Encouraging results respect-

Nitrogen-enrichment of soil due to the growth of clover

	Nitrogen Percentage in water- free soil.	Lb. per acre to a depth of 4 in.
Before experiment	0.0437	538
After two years	0.0580	708
four years	0.0608	742
five years	0.0689	841
six years	0.0744	908
seven years	0.0750	916
nine years	0.0824	1,005
ten years	0.0858	1,044
Increase in nitrogen due to ten years' growth	0.0419	511

ing the economic use of manures, fertilisers, and crop rotations have been obtained. As an illustration the following practical results may be cited.

Potato growing is a specialised branch of agriculture in many districts of the Maritime provinces. This crop, it has been found, responds markedly to the application of commercial fertilisers, the data showing that a "complete" fertilising mixture will, as a rule, give the most profitable results. Generally, a mixture of sulphate of ammonia and nitrate of soda as sources of nitrogen in the mixture has given a better return than if the nitrogen is supplied from one of these chemicals only.

Experimental work in the apple-growing districts of Nova Scotia has demonstrated that profitable results follow the application of fertilisers. The question more particularly studied at the present time is the furnishing of available nitrogen during the early spring. Indications are that this practice may be generally adopted with satisfactory results.

In connexion with the question of liming, now a prominent one in Canada, a somewhat comprehensive survey has emphasised the importance of this practice for many districts in Quebec and the Maritime Provinces—Nova Scotia, New Brunswick, and Prince Edward Island. Remarkable responses have been obtained from the application of ground limestone and other forms of lime, particularly for the growth of clovers.

Investigation of Irrigable Lands in Southern Alberta and South-Western Saskatchewan. Certain of these lands are impregnated with "white alkali," and for ten years their examination formed a large and important part of the Division's investigatory work. The soils of all suspected areas were carefully analysed to a depth of 5 feet, and no quarter section was released for cultivation unless the evidence as regards saline content was satisfactory, i.e. that the impregnation was either nil or negligible. Incidental to this classificatory work, certain special investigations were necessary, and the problems studied have been reported in papers and bulletins, entitled "The vertical movement of alkali in heavy clay soils," "The 'alkali' content of soils as related to crop growth," "The nature of burn-outs," and "Alkali soils—their nature and reclamation."

The Chemistry of the Cereals.—Chemical work has gone hand-in-hand in the wheat-breeding investigations instituted by the late Dr. Wm. Saunders in the earliest days of the Experimental farms. These culminated successfully in the origin of the now famous Marquis wheat and its establishment as the premier wheat of North America. In this work numerous problems relating to the nature and composition of flours and their bread-making qualities have been studied. The results obtained have greatly assisted in the identification and isolation of new varieties of wheat with high

milling qualities, and, what is of almost equal importance, the elimination of those found to be inferior.

The high milling quality of Canadian north-western wheat and the outstanding "strength" of the flour therefrom are facts generally recognised in the wheat and flour markets of the world. The character or quality of gluten is essentially an inherited factor, but a systematic study of the question has shown that seasonal and soil factors have a marked influence on both the quantity and quality of this important constituent. The data from an investigation to determine the influence of environment carried on at a number of points throughout the Dominion indicate that a rapid development and maturation of the berry tend to produce a grain of high protein content and of excellent milling quality. Moisture and temperature conditions during the filling out of the grain markedly affect its composition. If there is a sufficiency of moisture in the early part of the season to bring the crop to a good growth, then a fairly dry soil and high temperature during the later weeks of the season hasten maturity and conduce to a hard berry with a high protein (gluten) content. These conditions usually obtain over the larger portion of the wheat belt of the great North-west. It may therefore be concluded that the high quality of the wheat of the prairie provinces is not merely a result of heredity and a rich soil, but in a large measure is due to the favourable meteorological conditions which, as a rule, characterise the growing and ripening seasons in North-western Canada.

The Beet Sugar Industry.—The influence of seasonal and soil conditions on the quality of sugar beets grown in various parts of the Dominion has been systematically investigated since 1902. Seed of high sugar varieties—imported and Canadian grown—is being annually sown on 21 of the farms and stations of the Experimental Farms System situated in the several provinces and representative roots from the harvested crop are analysed. Leaving out the data from the points in the northern parts of the prairie provinces where the autumn temperatures are too low for a proper ripening of the beet—the averages for last year are: sugar in juice 17.5%, with a coefficient of purity of 86.0.

This inquiry has afforded satisfactory evidence of the possibility of growing in many widely distant districts of the Dominion beets of excellent quality and eminently suitable for sugar extraction. It has also shown that Canadian grown seed can produce beets fully equal in sugar content and purity to those from imported seed of the most approved European varieties.

There are to-day in Canada two beet sugar factories—one in South-Western Ontario, the other in Southern Alberta—both operating successfully and profitably alike to grower and manufacturer.

Soft Pork: Its Character, Causes and Prevention.—Among the qualities necessary for first-class bacon for the English market none is of greater importance than that of "firmness." A tendency to softness will rate the bacon at second-class prices; a pronounced softness makes it unsaleable at a profit.

An investigation to learn the nature and cause or causes of softness and to suggest preventative measures three years and involved the feeding of more than 300 and the chemical examination of the fats therefrom. It was found that the fat of "soft" bacon contains

a much larger proportion of olein than that of "firm" bacon; in the former the ratio of palmitin plus stearin to olein is 1 : 4; in the latter about 1 : 1.75.

The experiment was planned to ascertain the effect on quality of the pork of such factors as maturity of animal, character and supply of food, exercise and lack of exercise. From the results of the experiment it was concluded that the fat of young pigs and animals of unthrifty growth is softer than that of finished pigs. Immaturity from whatever cause is a salient factor in the laying down of "soft" fat. The character of the food is an important factor. Indian corn and beans fed injudiciously tend to produce soft pork. Fed in conjunction with skim milk a considerable proportion of corn may be used without injurious effect. A grain ration, in equal parts of oats, peas and barley, gave firm pork. Skim milk promotes thriftiness and rapid growth with consequent firmness of pork.

Insecticides and Fungicides.—In addition to the examination of insecticidal and fungicidal sprays, dusts and allied materials found on the market, for the purpose of determining their purity, strength and suitability, a considerable amount of research work has been carried on in close co-operation with members of the Entomological Service with a view to correlating laboratory results with practical experience in the orchard. This work has been most fruitful: a marked improvement in many brands of arsenicals has resulted. The danger of leaf scorching has been practically eliminated. The search for insect poisons other than arsenicals is in progress, and has already met with some success.

The degree of persistency of arsenic, from sprays and dusts to foliage and fruit is being investigated. Results are proving helpful in drawing up directions to orchardists in the use of these materials whereby the danger from this source will be greatly lessened.

A variety of oils is now being used in spraying preparations, and through the co-operation referred to, the relation between chemical and physical properties and their practical effect in the orchard is being ascertained.

The Fertilising Value of Rain and Snow.—For seventeen years continuously a research was conducted, analysing every fall of rain and snow, to determine the amount of nitrogen in free and albuminoid ammonia and in nitrates and nitrites, washed out of the atmosphere by the precipitation. The average annual rainfall at Ottawa, Canada, is 24 in., snowfall 96 in., a total precipitation of 33.6 in.

This inquiry has shown that snow is decidedly poorer in nitrogen compounds than rain, the total nitrogen content of snow being practically one half that of rain. The average amount of nitrogen, at the point of collection, furnished annually was found to be 6.9 lb. per acre—an amount equivalent to an application of approximately 44 lb. of commercial nitrate of soda.

The allotted space is filled, and mention of many important lines of research in agricultural chemistry must necessarily be omitted. In this brief sketch it has only been possible to touch here and there on this work in the Dominion, but it is hoped that sufficient has been written to indicate its character and scope and also to show that Canadian governmental authorities are alive to the value of scientific research as applied to Canada's fundamental industry of agriculture.

Plant that's three-times sound

FIRSTLY whether the process is the sulphonation of β -Naphthol, the refining of Mineral Oil, the evaporation of Tomato Juice or the sorting of Feathers—designed soundly for the work it has to do.

THEN built soundly. Not merely heavily constructed, but skilfully wrought to stand up economically to the known requirements of the process, and maintain steady output at high efficiency over long periods. Each is an engineering job.

AND, where users desire this, the plant is erected under the direct control of the builders—handed over as a complete production unit.

SOUND in design, manufacture and erection, and proved by nearly a century's experience in every part of the world—such is Fraser Chemical Plant. Send a card now, telling us what processes interest you most, for the catalogues dealing with your own industry. *Let your next plant need be dealt with in this same sound way.*

These reagents from Greenwich, England save time and increase accuracy in analytical work.

*Sofnolite —the new
gravimetric CO₂ absorbent.*

SOFNOLITE is the new gravimetric CO₂ absorbent which replaces messy, fragile Potash Bulbs. It is a simple matter to fill a U-tube with dry, granular SOFNOLITE; the colour change shows when absorption is complete, and the results are absolutely reliable. There is no loss of moisture during use no following drying tube is needed—thus you save a weighing.

SOFNOLITE, packed in 1-lb. bottles, costs only 3s. 6d. per lb. (carriage abroad extra). **British—cheapest—best.**

We are the actual makers of a full range of the newer acidimetric indicators for greater delicacy and accuracy than is possible with Methyl Orange and Phenolphthalein. Our booklet, "Indicators for Accurate Titration," shows the advantages of these modern indicators. We shall be pleased to send a copy, post free, to any Chemist.

OUR manufactures include:—Soda-lime (with and without catalysts); Sofnolite; Indicators—Sofnol Indicator No 1, Sofnol Indicator No. 2, Thymol Blue, Bromo-Thymol Blue, *m*-Naphtholphthalëin, *o*-Cresolphthalëin, Diethyl Red, Methyl Red, Ethyl Orange, Methyl Orange, Pnenolphthalëin, Pheno-saffranine, etc.

Water Testing.—Sofnol Special Soap Powder and Solution, and other reagents for water testing; Special apparatus which greatly simplifies this work; The Sofnol Syphon Burette. All of these are described in an interesting series of free booklets. Let us know now which of these we shall post you.

THE PULP**PAPER INDUSTRY
ADA****OSS, B.Sc., F.R.S.**

In the Canadian pulp and paper trade we have an industrial development as great as any within the boundaries of the Empire, which, in total capital invested, is second only to that of the electric light and power plants of the dominion, and in respect of labour involved second only to that of the saw mills. Canada has not been so prodigal as the United States in respect of its indigenous supplies of raw material, mainly coniferous woods, and the Dominion Bureau of Statistics in their publications make it evident that the forest supplies are under systematic control by a trained service of competent experts, such as will ensure a continuous and methodical exploitation of this vast wealth. At the same time, no definite Government afforestation system has been adopted. So far, it is in the hands of the large owning companies to work the best-known systems in their own interests and in replacement of the old exhaustion practice under which the smaller companies moved their mills as they exhausted the wood supply of the areas occupied. Clearly there is no virtue in this degree of afforestation other than that of mere necessity. But it may be anticipated that, before long, public opinion will initiate a compulsory national system of afforestation which will be on a wider and more systematic basis: there is, in fact, no essential reason why conifer forests on a system of scientific forestry should not actually increase as fast as, or faster than, the demand increases. In this connexion it is of interest to record a report that Canada has been very recently enjoying a national festival designated "Forest Week," the celebration of which indicates to the discerning spectator the rise of a tide of public interest that will assuredly have an enormous and permanently beneficial effect on the future development of the industries here in consideration. Another interesting sidelight is presented by the rapidly increasing use of aeroplane patrols for reconnaissance duties of fire prevention.

A special publication of first importance is a serial record in the form of a Census of Industry, and the volume for 1925 is an exhaustive and concise account of the industrial developments connoted by the title: *The Pulp and Paper Industry (1925)*, Ottawa, Government Publication, 1927.

A few examples of growth may be selected. The most prominent name in the industry is, perhaps, Riordon. Members of this family were amongst the pioneers of the ground wood pulp industry, as of the bisulphite (cellulose) industry, Charles Riordon having installed the first mill at Merriton, Ontario. Following this lead, five mills are reported, in 1881, with a capital of \$92,000, and an output valued at \$63,300 per annum. Since then growth has been rapid; in 1891 to 24 pulp mills; at the present time to 45 mills with 35 combined pulp and paper mills.

The net value of production and increases are shown by the following figures:—

1921	84,523,283
1922	93,508,104
1923	113,091,953
1924	107,025,628
1925	116,577,947

It must be remembered, in pursuance of statistical results, that the constituent provinces of the dominion are of very unequal importance in the industry. Thus, of 115 total mills, Quebec and Ontario claim 95: Nova Scotia, New Brunswick, and British Columbia are of only fractional importance. In a statement such as the present, however, it would be gratuitous to attempt to cover the ground of the excellent publication cited. For the expenditure of 25 cents, this means of well-ordered statistical information is to be acquired and the concentration of matter is such that the whole subject is dealt with in some 60 pages.

It is of more interest to present-day workers to follow particular lines of development. In the perspective of the industry, the inter-Canadian-American trading figures are important, for they have obviously a further and political significance. The United States are the largest customers of the Dominion, and the following figures give an impression of the dimensions of this trade.

	1925	1926
Paper, total	\$ 95,000,000	103,000,000
Newsprint cwt.	26,500,000	32,500,000
Paper board	\$ 1,900,000	1,600,000
Wrapping papers cwt.	768	3,858
Pulp wood, in cords	1,400,000	1,400,000
Pulp wood mechanical	5,600,000	5,100,000

It is important to know, in elucidation of these figures, that a very large capital is invested from the United States, American firms finding it advantageous to produce their raw and half-manufactured materials over the border and import them to their factories in the States, to be there manufactured into paper boards, and other commercial forms of the multifold "cellulose" industry. Thus the Brown Co. of Berlin, N.H., one of the most powerful firms in the industry, are conspicuous in exploiting this border trading, drawing their supplies (which are stated to be some 400 tons a day) of cellulose and ground wood or "mechanical" pulps) from this source. In the field of the more specialised cellulose industries the Brown Co. have devoted their research equipment to the special refinement of the pulps produced by the bisulphite processes to meet the requirements of artificial silk manufacture: they have produced an "alpha pulp" which in composition and characteristics is an approximation to those of bleached cotton. This pulp is steadily advancing in replacement of competing sulphite pulps on the basis mainly of its high percentage of the alpha cellulose, which is some 7-8% above the highest alpha content of the pulps directly produced for the paper industry.

The Riordon Co. the lineal successors of the early pioneers of the Canadian industry—have more specially studied the qualities of pulps in regard to paper making, and have been specially successful in standardising

a number of brands which are recognised and accepted as giving papers of special qualities. This company also has perfected special makes of pulp adapted to the requirements of the artificial silk industry.

These are only particular instances of developments which have been "latent" or potential ever since the first production of the "sulphite pulps" in 1878-82. It is evident that the bisulphite process during these 50 years of massive production has been rigorously standardised in respect of the dependence of the qualities of the product upon the condition of the process; it is a special example of the enormous range of variations of quality of a natural raw material that are realisable under methodical study—the combined study of observation chiefly of external qualities, by factory workers and the deeper observations of the research staff in studying the material in relation to first principles. As might be expected, the greatest portion of the total output to-day is sulphite pulp containing up to 80% of ground wood pulp (so-called mechanical pulp) for newsprint. The output of this product has grown very rapidly: the first ground wood mill at Valleyfield, Canada, had a turnover of 2 tons a day: the large mill of to-day will turn out 490 tons a day. In about 10 years this product has quadrupled in output, and it is to-day about 2 million tons per annum. Its future growth is bound to be also very great, and to reach ultimate dimensions which cannot be visualised, though it is discernible that successful afforestation is going to be an ever-increasing condition of success in this branch of the industry. Spruce is, of course, the wood most particularly concerned in this output, and the quantity of it consumed is now three-quarters of the quantity of wood consumed in the whole of the cellulose industry of Canada. The figures for 1924 and 1925 are:

	1924	1925
All wood cords	3,316,951	3,668,959
Spruce.. "	2,284,230	2,608,723

The bisulphite process dominates the newsprint output, and must, therefore, continue to be the process most largely in use. Its other field of interest, now exciting much attention, is the production of high grade pulp for the viscose silk industry, and in this connexion it will be recalled that the Chairman of Courtaulds at their recent Annual General Meeting announced that the new mill of that company at Cornwall, Ontario, has now been working for 12 months on full output and with very satisfactory results. It may be anticipated that future developments in this field will be of great importance and interest: some day, no doubt, the production of alpha pulp may come to be classified as a separate item in the statistics of the future to accord with the then importance that may be expected for this grade of material, though as yet it amounts to only a small percentage of the total sulphite output, and has not yet attained rank as a special statistical item.

The soda process, the oldest of the pulping processes, was also the first to be employed in Canada: its importance is now, of course, subordinate and perhaps comparable with that of the esparto pulp industry of

Great Britain in the provision of soft bulky papers. The sulphate process is of comparatively recent importance in Canada, the first mill being that at East Angus in Quebec opened in 1907. A number of woods are treated by this process: for the production of Kraft papers more particularly. But the output of the soda process and the sulphate process taken together are no more than about 10% of the whole pulp output; the following are the figures:—

	1924	1925
	Cords	Cords
All processes	3,316,951	3,668,959
Mechanical	1,448,280	1,619,159
Sulphite	1,520,319	1,642,324
Soda and sulphate	348,352	407,491

A good deal might be said about the change of condition produced by modern developments of machinery: thus the size and speed of the machines turning pulp into newsprint has increased enormously; the greatly increased daily output as compared with early days is, of course, closely related to these improvements of machinery. Amazingly effective as these improvements of machinery undoubtedly are, it would be hazardous to suggest that even still greater improvements are improbable in the future. However that may be, it appears fairly safe to prophesy that the future of this industry is going to be related to developments of machinery, to scientific control of the forests and the provision of capital for afforestation, and above all to the ever continuous research work of the laboratory, developing and elaborating new methods and new uses, which must, in the final analysis as it always has been, be based on deeper and deeper study of all the materials concerned.

FINE CHEMICALS IN CANADA

By T. H. WARDLEWORTH

Whilst there are considerable developments in heavy chemicals in the Dominion, there is comparatively small advance in the production of fine chemicals.

Salts of iodine and bismuth are still being made of fine quality, and at prices which enable the manufacturers to compete fairly well with the imported goods. There are, however, sporadic outbreaks of cutting from outside which disturb the market.

Hydrogen peroxide used to be a product of some importance, but since the introduction of the concentrated solution the manufacture in Canada has languished.

Acetylsalicylic acid and hexamethylenetetramine, largely made in the country during the war, have succumbed to the pressure from outside, and do not now figure largely on the list of products, if at all.

Ethyl chloride, ethers and chloroform are produced by one firm still, but the output is crippled by the restrictions of the Excise Department, which demands a tax of 33 c. per proof gallon on alcohol used for the manufacture of these products. This raises the costs to such an extent that competition from foreign countries which do not tax such alcohol does not permit of any great expansion in the output.

Diarsenol, neodiarsenol and sodium diarsenol are still being produced successfully by a Toronto firm, which is adding to its products gradually.

Insulin is also being produced, very naturally, in Toronto, under the supervision of the University authorities, and its distribution is controlled by them in such a way that it may reach the sufferers at the lowest cost.

Naturally the country looks to the Canadian Electro-Products Co., of Shawinigan Falls, for the leading developments in connexion with new chemical compounds. It is now manufacturing ethyl acetate from acetaldehyde. This process has been well known for some time from a scientific standpoint, but a commercial process has been worked out by the company, and it is now able to supply practically all the Canadian demands. The reaction is carried out in the presence of aluminium chloride and two molecules of acetaldehyde are condensed to give one molecule of ethyl acetate in accordance with the following equation:—

The Canadian Electro-Products Co. is also producing butanol and butyraldehyde from crotonaldehyde by the hydrogenation of the last named. These products are of prime importance as solvents for the lacquer now so much in demand. We may with confidence look for further advances by this company in the furnishing of new products at an early date, as its able chemists are constantly seeking new methods for extending the field of their work, either in creating new combinations or improving old ones.

Malic acid has been put forward as an article which could be manufactured in Canada as a by-product resulting from the making of maple sugar, but there seems to be no demand at present, so the interest in it has flagged so far. Some day probably a use may be found for it, and then its production may be commercially profitable.

Casein is made in various centres, and is being employed in the paint, paper and other trades with advantage. A fine grade is also being used in diabetic foods—a plant has just been established in the Dominion for the purpose of preparing a flour with this basis.

The quantity of sugar of milk made in Canada is becoming larger as time goes on—the makers handling this article are sending forth an excellent grade. There is every prospect of a wider market for this industry in Canada and possibly for export.

For a time the German fine chemicals had the benefit of the depreciated currency ruling in Germany, but that is not so apparent now, and the balance has gone more in favour of Great Britain and the U.S.A. The advantage the Teutons possess now seems to be in the lower freights from their country compared with the high ocean rates from the United Kingdom to Canada. Owing to the general keen competition, this factor frequently turns the scale in favour of Germany or some other Continental country.

Aniline dyes are now being made in Canada, and there is a prospect that the growth in this direction will be speedy.

Industrial alcohol is being distilled in larger quantities

as new avenues are being opened for its use—especially in making combinations for lacquer solvents.

Medicinal and pharmaceutical preparations are following largely the usual lines, and the Department of Health is watching carefully that the modern standards are rigidly observed. Upon the whole, it may be said that high-grade preparations are the rule all over the country.

CHEMICAL ENGINEERING IN CANADA

By PROFESSOR L. F. GOODWIN

To survey the chemical engineering activities of Canada in a short article presents considerable difficulties, since these range from the crude attempts to distil bitumen and oil from the tar sands of Alberta to the modern and efficient plants of the East. Some of the biggest and most modern plants in Ontario and Quebec are subsidiaries of English or American companies, such as Brunner Mond's and Courtauld's, or represent enormous sulphite mills, such as the Laurentide Co. and Price Brothers. Their methods and constructional details are familiar to English readers, and the writer therefore proposes to give as general a survey as he can of more typically Canadian activities.

PLANT DEVELOPMENT

The present and future field lies in the application of physics, physical chemistry and engineering to plant design; that is, chemical engineering. Existing processes have to be improved, waste products—including more especially waste heat—have to be utilised, and new processes translated to plant scale. With the high and increasing labour costs on this side, the tendency is more and more towards mechanisation and automatic control.

An adequate survey being impossible, one or two industries will be chosen as illustrations. Few better examples of first-rate chemical engineering can be found than the new plant of the Canadian Cellulose Company at Cornwall, Ontario, which the writer visited a few weeks ago. Designed, erected, and now being put into operation by Mr. G. H. Tomlinson, all within a year, it is a model of design. It is intended to demonstrate that with modern methods and equipment soda pulp can be made so as to compete with sulphite. And since scientific method is lacking in many sulphite mills success will lie with the chemical engineer.

Two digesters of 50 tons daily capacity are installed and equipped with external heating by the Morterud system. A special feature here and elsewhere is the use of hydraulically-operated valves. Oliver filters are used to separate the black liquor from the pulp, which is then again diluted and carried to a special set of screens, consisting of a drum rotating within an octagonal chamber, this combination imparting a peculiar pulsating motion to the stock. There are the usual additional screens and devices for rejects during the chipping, washing and screening operations.

Bleaching is carried out in three vats lined with white tiles, provided with screw conveyors for the pulp and with ingeniously controlled valves. An electrolytic soda and chlorine plant is installed, but with the anticipated efficiency in soda recovery in the calciners, little

make up soda should be required. A new type of dryer is in use, designed to economise in steam consumption. This is effected by subjecting the pulp web to pressure between heavy corrugated rolls, squeezing out as much water as possible before passing it on to the drying rolls. All pulp produced in the digesters is thus treated irrespective of its subsequent destination, thereby effecting great economy of labour and handling throughout the plant.

The soda recovery system is of the modern type, with many improvements. The black liquor and washings, part of which circulate in the causticising cycle, are taken to quadruple effect evaporators and evaporated to the utmost practical consistency. The concentrated black liquor is then sprayed into a modern type of calcining furnace, where it is burnt and the molten soda ash tapped off at the bottom and sent to the green liquor tanks. The waste heat gases go through a tunnel where they impart a final concentration to the incoming black liquor, and pass on to two waste heat boilers, and then through a scrubber into the atmosphere. In efficient mills the heat thus generated more than suffices to run all operations. A large rotary kiln is used to burn the calcium carbonate sludge. The green liquor is causticised by means of lime in a continuous and automatic fashion, the white liquor and sludge passing through two Dorr thickeners, and then through special tanks where its specific gravity, head, and quantity are automatically controlled. Oliver filters handle the calcium carbonate sludge. The plant sprang, like Minerva, finished from the head of its designer, necessitating no changes of plan, and resulting in great economy of space and erection costs. It is to be hoped that the Howard Smith Paper Company will continue to avail themselves of research in the running of this mill.

The plant of the Aluminium Company of Canada at Arvida is an example of production on an enormous scale. Electric current being the chief requisite, the parent company at St. Louis decided to ship its purified raw material, aluminium hydroxide, to the source of supply, the new electric development at Chute-a-Caron, where upwards of a million horse-power are being developed. As it is only a twenty-mile railway haul to Port Alfred at tide-water, ultimate shipment by water of foreign bauxite for the manufacture of pure aluminium hydroxide is a future possibility. The site was undeveloped farm land, but within a year a whole town and factory have sprung into being.

The process used is the electrolysis of alumina dissolved in a molten bath of cryolite. The aluminium hydroxide is made in the requisite degree of purity by the Bayer process, and the individual electric furnaces or pots consist of a baked carbon lining supported by an outside steel shell. Forty furnace rooms are contemplated, each containing one hundred pots. The company make their own electrodes from pitch, petroleum coke and electrode scrap, and the electrode baking furnaces, according to a recent statement in *Chemical and Metallurgical Engineering*, measure 10 by 10 by 200 ft. In order to handle the enormous quantities of raw materials, the works-railway both in and out doors is of standard gauge using full size cars. The crushing, grinding and conveying plants are on a corresponding

scale; thus the storage building for petroleum coke measures about 150 by 400 ft. No precise information is available as to the plant's output, but this could readily cover the world's production of aluminium, at present estimated at 150,000 tons annually.

In this example of modern chemical engineering we find raw or partially manufactured materials transported thousands of miles to the source of cheap electric energy, from whence the finished aluminium is again sent out to the various countries of the world—of course chiefly to Canada and the United States—to be manufactured into various articles.

An older but none the less famous example is to be found in the manufacture of acetic acid and acetone from calcium carbide at Shawinigan Falls. Born during the stress of the war years, this process was pushed to its present large production almost from the start, Mr. H. W. Matheson realising that the exigencies of war could not wait for the usual semi-plant scale experiments of the laboratory. Taking risks and incurring explosions, the conversion of acetylene to acetaldehyde was carried out in large aluminium and other vessels, and proved successful. The plant is now facing the post-war adaptation period so well known to works in England.

NEW PROCESSES

It is not only in the development of known processes that chemical engineering has played its part in the Dominion. Two new processes based on chemical and electrochemical research are worthy of notice. One is the production in the electric furnace of sodium sulphide, worked out on a manufacturing scale by Mr. H. Freeman at Shawinigan, and the other the production of titanium oxide from ilmenite by Mr. R. H. Monk and associates. A large production is contemplated for the latter process. It is with regret that the writer must forbear to mention other instances.

ELECTRIC STEAM BOILERS

This typically Canadian development must not be overlooked. Many works, particularly pulp and paper mills, contract for large blocks of electric power on a 365 days a year basis. If, for any reason, part of the plant is temporarily shut down, the electric energy thus laid waste is now utilised in an electric steam boiler developed by the Shawinigan Company. Units of 4000 kw. and over are in regular and satisfactory use, require little space and less attention, and contribute their quota of steam to the works power plant, resulting in a saving of coal.

NEW PROBLEMS AWAITING SOLUTION

Mention should be made of two, both of which will require chemistry and engineering for their solution. The lignite or brown coals of Alberta present an urgent problem, and await a satisfactory process of carbonising and briquetting. Intensive work has been done with large scale retorts and voluminous reports published of the progress made, but an adequate solution is still to be desired.

The bituminous tar sands of Alberta, containing up to 15% of bitumen, and comprising hundreds of million-

of tons, still await a chemical engineering wizard, in spite of the fact that at least one simple and adequate physical-chemical method of separation has been invented. In this instance, as is the case with the large western deposits of Glauber's salts, transportation costs are a main obstacle to utilisation.

UNIVERSITY DEVELOPMENT

The three big universities of McGill, Toronto and Queen's have for many years given courses leading to the B.Sc. degree in chemical engineering. The fundamentals common to all three are courses in chemistry, physics, mathematics, thermodynamics, structural and mechanical engineering, hydraulics, metallurgy, industrial chemistry, chemical engineering, both as regards processes and plant design, and engineering economics. All three universities have recognised that training in engineering must be taken *together* with training in chemistry to avoid specialisation in chemical subjects only. A graduate in pure chemistry only is generally unable to adapt himself to engineering thought and calculations when subsequently attempting a fifth or sixth year in engineering, and trying to become a chemical engineer. The lecture and laboratory work are of a uniformly high order, but only Queen's University has a laboratory specially devoted to chemical engineering. It may be added that the writer is opposed to the waste of time and money caused by the installation of too large units, and believes that chemical engineering plant at Universities should be of the minimum size necessary to teach the fundamental principles involved. Large-scale operations are taught best in works, the principles must be studied in the laboratory. The greatest developments in the future must be in the improving of yields and of new and existing processes. The chemical engineering students turned out by these universities have no difficulty in holding their own in works, and unfortunately too large a number find ready employment in the United States.

PROFESSIONAL SOCIETIES

Mention must be made of these. In Canada, too, the chemists and chemical engineers have felt it necessary to organise in order to establish their professional and public status. But, as in other countries, order has still to be evolved out of the chaos of conflicting societies. The problem is particularly serious in this far-flung Dominion, where you may travel eight hundred miles by rail, and know there are only two chemists in that section.

The Canadian Institute of Chemistry, established for nearly eight years, has a membership of over three hundred, and the majority of chemical engineers belong to it. The Engineering Institute of Canada or its affiliated branches, such as the Professional Engineers of the Provinces of Quebec and Ontario, attract a smaller number. Many, of course, belong to the Society of Chemical Industry, but are not numerous enough, nor do they deem it expedient to form a chemical engineering group. Others, again, belong to the Pulp and Paper Association and kindred societies. The present duty of the chemical engineer seems to lie in contributing to as many chemical and engineering societies as his purse will permit. Possibly a general Canadian chemical

association, which is now being discussed, can link the various conflicting elements together.

Dept. of Chemical Engineering,
Queen's University, Kingston

CANADIAN INDUSTRIAL NOTES

A syndicate formed of Americans, who formerly operated distilleries before the Volstead Act became law will erect a large distillery for the manufacture of Canadian and American whiskies, alcohol and by-products, at Sarnia, Ontario, opposite Port Huron, Michigan, on the St. Clair River.

The Manitoba Pulp and Paper Co., Ltd., has begun the construction of a new 250-ton paper mill at Pine Falls, Man.

McGill University has decided to establish a department of industrial medicine, with which will be associated a clinic for industrial diseases at the Montreal General Hospital.

The Canadian Salt Co., Ltd., in its financial statement for 1926, shows operating profits at \$342,905, compared with \$346,411 in the previous year. After allowing deductions for bond interest, patent rights, depreciation and income-tax, the balance left available for dividends was \$161,460. Profit and loss account stands at \$305,463.

Port Alfred Pulp & Paper Co., in its financial statement for the year ending December 31, 1926, shows gross operating profits of \$1,260,929, as compared with \$921,935. After allowances for depreciation, depletion and payment of preferred dividends there remained available for company stock the sum of \$276,629, equivalent to \$2.30 per share on 120,000 shares of no par value common stock.

The International Nickel financial report for calendar year 1926 gives net profits as \$5,556,267 after necessary deductions, equivalent to \$3.00 a share (par \$25.00). The previous report was equal to \$2.29.

The annual financial statement for year, ending December 31, 1926, of the Abitibi Pulp & Power Co. shows profits, after payment of preferred dividend, equal to \$11.56 per share on the common stock, as compared with \$11.19 in 1925.

The earnings of the Howard Smith Paper Mills, Ltd., showed an improvement for the year 1926. Net profits for the period were equal to 7.62% on common stock as compared with 4.74% in 1925. Operating profits for the year were the highest since 1920. The depreciation reserve reflects substantial additions made during the past few years, now being shown at \$2,423,620.

Canadian Cannery, Ltd., show a moderate increase in gross and net earning during the calendar year 1926. The net profit, after all deductions, was \$539,401, compared with \$480,271 in 1925. Dividends at 4% absorbed \$364,568.

In its financial report for 1926, the British Columbia Fishing & Packing Co., Ltd., showed net profits of \$499,294, after making usual deductions and ample provision for reserve. This is equivalent to \$10.02 per share on the issued capital stock.

THE MANUFACTURE OF NICKEL BY THE MOND NICKEL COMPANY, LTD.

INTRODUCTORY

When we consider the manufacture of nickel and the many alloys and compounds of nickel, and the innumerable articles of which nickel forms some portion, we realise how large a part the British Empire plays in this industry, and how modern, how necessarily modern, is the industry. Nickel and its alloys have a number of qualities of hardness, toughness, brightness that does not tarnish, and so on, which make them of use in an extraordinary variety of cases. The condition in which the metal exists in its ores makes its extraction not at all an easy matter; and it is only in quite recent times that

its name; we are informed that the word "nickel" means "obstinate devil," and that the saving in space justifies us all in making use of a German word of six letters instead of English words of many more. The ore is mined in Canada, and partially treated there; the extraction of the metal is completed in Wales; the alloys are made in Birmingham; the malleable pure nickel is made there, and there also are made the rods, wires, plates, and sheets of nickel itself and many alloys. This great British industry is very largely due to the vision of the late Dr. Ludwig Mond, F.R.S., and Dr. Carl Langer, who devised the process and made it a commercial success; we confess that we are hardly surprised that, when the scientific skill of Dr. Langer had indicated a method the obstinacy of the

FIG. 1

Furnace and Converter Building, Coniston Smelter, Ontario, Canada

such an extraction has been economically possible. Moreover, its resistance, and that of its alloys, to corrosion, to fatigue, to temperature, and to general wear and tear, is so great that it is only the stress of the present time which requires the frequent use of so remarkable a metal. Even had it been far more abundant it would not have been of importance until the age of electricity, high-speed tools, armoured ships, motor-cars, and wireless. It is no metal for the primitive, the mediaeval, or the old-fashioned man. It is a metal for the modern man, but until we visited the works of The Mond Nickel Company, Ltd., at Clydach, and those of its associated company, Henry Wiggin & Company, in Birmingham, we confess we very imperfectly realised how many are its uses.

The nickel we saw has nothing foreign about it except

nickel had to yield to the persistence of Dr. Mond, for he was a very determined man, not unduly tolerant to men or metals who tried to oppose his will. It was in 1889 that he and Dr. Langer found out that carbonic oxide will combine with finely divided nickel to form the gaseous nickel carbonyl $\text{Ni}(\text{CO})_4$, which readily decomposes on moderate heating to form pure nickel and carbonic oxide. It took ten years to make the process a commercial success, secure the raw materials, and create The Mond Nickel Company, Ltd. The time and money thus spent have been most fully justified. The development of modern technical methods is a task for those who have abundant time, money, patience, and determination; those who criticise our British manufacturers for their timidity in handling new inventions should bear this fact in mind. The ores come from a

small number of mines near Sudbury, Ontario; they undergo a preliminary treatment at Coniston, near Sudbury, and the plant there was begun in 1912 and finished in 1913, though operations on a less ambitious scale had previously taken place at one of the mines. The product of this preliminary smelting is a matte containing about 41% of copper, about 41% of nickel, about 17% of sulphur, and less than 1% of iron: this matte is shipped to Swansea, and the pure nickel is prepared from it at Clydach.

CLYDACH

The works at Clydach are pleasantly situated just outside Swansea; they are well planned, on modern lines, with ample room for even further additions and extensions.

this reduces the nickel oxide to the state of metal, and the finely divided material is then passed through conveyors to "volatilisers," maintained at a temperature below 80° C. Carbonic oxide is led through the "volatilisers"; it combines with the nickel and the gaseous nickel carbonyl, thus formed, passes into tall cylinders partly filled with pellets of nickel of varying sizes. These cylinders, or "decomposers," are kept at a temperature of 180° C., and the nickel carbonyl breaks up, depositing pure nickel in thin films on the pellets already in position. The pellets gradually grow in size, and when they are about as large as peas they are automatically removed. It is no rapid process, this deposition, for it takes several months to grow a pellet as large as a pea. The carbonic oxide released in the

FIG. 2

General view (looking north) of the Works of the Mond Nickel Co. at Clydach, S. Wales

in the immediate vicinity are convenient and pleasant-looking houses, many of which have been built by the Mond Nickel Company for the accommodation of those employed in the works.

The process used is comparatively simple in the laboratory, but its amplification into an economical works operation is a matter of considerable difficulty. The matte, a mixture of nickel sulphide and copper sulphide, is crushed and roasted, yielding a mixture of impure oxides; this mixture is treated with sulphuric acid sufficient to dissolve the greater part of the copper but leave the nickel unaffected. The copper-sulphate solution is filtered off and allowed to crystallise, the process working continuously and almost automatically. The solid matter left after treatment with sulphuric acid is washed and dried and then treated with water-gas rich in hydrogen; at a temperature rather under 400° C.

"decomposer" travels again and again in the cycle. The residue left in the volatilisers, consisting of nickel and copper, is mixed with the original matte and returned into the process, so that there is very little waste; in fact, the only waste is the loss of the sulphur in the matte and the hydrogen in the water-gas.

South Wales contains towns, which, like other towns in Great Britain, were built in the days of ignorance, when people imagined that because a few people can cheerfully sleep in hovels in a country where they work all day in the fresh air, therefore many thousands of people can live in hovels in a town and work all day in a pit or factory. The works at Clydach was built in a more enlightened age. Most parts of it are bright, airy and healthy, while there is evidence, in the shape of club-rooms, bands, athletic-sports, and such things, that the Mond Nickel Works is not, in any sense,

NICKEL ELECTRODEPOSITION

Form of product	General properties	Uses
Nickel and at Anodes (98-100% Ni)	Protection from corrosion Decorative appearance Suitability for thick adhesive hard and non-corrodible deposits	(Automobile and other parts exposed to weather household fittings, building as of machinery parts, etc.)

NON-FERROUS NICKEL ALLOYS

Type of alloy	General properties	Uses
Nickel-Copper-Zinc (Nickel Silver) (7-35% Ni)	White colour Brilliant polish Moderate tensile strength High ductility Resistance to corrosion Electrical resistance materials	(E.P.N.B. articles, spoons and forks, automobile radiator shells and fittings, ship fast fittings, telephone parts, electrical resistance, etc.)
Nickel-Copper (2-70% Ni)	High ductility Toughness Retention of strength at elevated temperatures Resistance to corrosion Special electrical properties White colour Brilliant, polish	(Bullet covers, spoons and forks, automobile radiator shells and fittings, condenser, tubes, marine fittings, catheters and similar uses, chemical plant, electrical resistance, etc.)
Nickel-Chromium (60-80% Ni)	Great strength at high temperatures Abnormal resistance to corrosion High electrical and thermal resistance Non-aging	
Foundry Alloys	Improved mechanical properties (Aerospace and automobile engineering)	(Electric wire and other electrical equipment, furnace equipment, structural materials, precision tools, etc.)

a mere collection of works managers and workers, making profits for directors and shareholders, who have no interest in their employees' well-being. There is a corporate existence and a spirit of community which we have noticed in other chemical factories, and the absence of which in many other industries we have deplored as a cause of discontent, suspicion and unrest. The chemical industry has so far a good record in this respect, it is to be hoped that it will maintain this record. The Mond Nickel Works at Clydach employs about a thousand men, and its capacity is about 10,000 to 12,000 tons of nickel a year in the form of pellets. It also turns out about 30,000 tons of copper sulphate crystals, chiefly used to spray the vines in the wine-growing districts of Europe, and a much smaller quantity of nickel sulphate and nickel ammonium sulphate crystals.

The Canadian nickel ores contain small quantities of the precious metals—silver, gold, platinum, palladium and the other metals of the platinum group. The method of extracting the nickel and of preparing the crystals of copper sulphate is such as to effect a concentration of these precious metals, and in the fulness of time they are separated and individually recovered. The process of making nickel appears, on the surface, possibly a simple one. The disposal of the nickel when it is made is far more complicated, and the Mond Nickel Company prudently entered into an arrangement with Messrs. Henry Wiggin & Co., Ltd., in Birmingham, who have for nearly a hundred years been accustomed to make up nickel alloys of various kinds.

NICKEL

In addition to the use of nickel for making ferrous alloys, copper alloys and chromium alloys, the pure metal is required in considerable quantity. To make nickel malleable or capable of being fabricated it is necessary to add to the molten metal a small proportion of magnesium metal, which removes the last traces of the deleterious oxygen and sulphur.

Many countries have nickel coins, for instance, Canada, Italy, Switzerland, Belgium, Poland, and Siam. There is a great demand for nickel in the form of anodes for electro-plating, and these are made in large numbers at one of Messrs. Wiggin's works. Pure nickel is also used considerably in wireless valves and to a limited extent for cooking utensils.

NICKEL-COPPER ALLOYS

Nickel-copper alloys have been known from time immemorial, and how the ancient Bactrians and the ancient Chinese made nickel copper coins more than two hundred years B.C. is still a matter for speculation. At the present time the majority of the civilised countries use nickel-copper coins containing 75% of copper and the rest nickel; among these are included Austria, Bulgaria, Denmark, France, Holland, Roumania, Japan, Egypt, Brazil and the United States. The envelope of the modern bullet is made of a nickel-copper alloy, and there is apparently a steady demand for these even in peace time. For electrical resistances a copper-nickel alloy, containing about 40% to 45% nickel, has been very largely used, and is known as "Ferry." Messrs. Wiggin make as well an alloy, of similar composition, which is

sold under the name of "Silveroid"; it consists of 45% nickel, 1% of manganese, and 54% of copper. This material is rolled into sheets and stamped into spoons and forks, fish-knives, and all kinds of table accessories. When you travel by train to Liverpool, watch the American summon her progeny to shredded cereal: it has been prepared on "Silveroid," and the progeny makes use of "Silveroid" for the disposal of the cereal; go to Paris and sample what a modern poet calls Foyot's sizzling *crêpes*; they are served on a nickel-copper alloy dish; the champagne from Jero-boams is distilling its argent spume upon the salted ice in a "Silveroid" cooler; you motor to the—shall we say Opera? in a car with many nickel-copper parts. Finally, *compère* and *commère* make their parting bow, the curtain drops upon the packed *coulisses*; the footlights darken suddenly, and now attendants claim their petit bénéfice, paid with good grace and paid in nickel-copper. Hotels, restaurants, kitchens, motor-cars, theatres, these consume quantities of nickel-copper, and we could, we think, write about these at considerable length. Does not Frankau say, "Science! not all your long research avails to staunch the flux of literary ranter."

"Corronil" is another nickel-copper alloy containing 70% of nickel, about 30% of copper and a trace of manganese. It is non-corrosive, and retains its strength at high temperatures. An alloy of this type has long been imported into this country under a well-known name. Now at last an entirely British product is available for the many chemical and other purposes for which this composition is so well suited.

NICKEL-COPPER-ZINC ALLOYS OR "NICKEL-SILVERS"

There are many of these, some of which are used for making silver-plated ware, spoons and forks, etc., but we fear to enlarge on the appliances for cooking, eating and drinking; there is an unending supply of verse on these topics, and we might be tempted.

NICKEL-CHROMIUM ALLOYS

We are glad to think that there is nothing frivolous or flippant about these; they call up no recollections of Gaby or Mistinguette; they are steady, well-behaved, purposeful alloys, just and tenacious. There is "Brightway," 20% chromium and 80% nickel; which with our own eyes we have seen cast and forged and drawn into wire. It is material of this type which is exclusively used for the heating elements of our domestic electric fires, ovens, irons, furnaces of various types, etc.; while for electrical resistances, for a number of special purposes, this alloy is finding a rapidly extending field of usefulness. The alloy is the strongest known at temperatures above 700° C. There is another alloy called "Redray" which contains 85% of nickel, and there are others yet, each with its own special mechanical, electrical and thermal properties. If you have a fancy for any particular number of microhms per centimetre cube as specific resistance you can, *exceptis excipienda*, be accommodated by Messrs. Henry Wiggin.

NICKEL-IRON ALLOYS

These alloys are also made in Birmingham. The 30% nickel alloy is used when strength combined with

non-magnetic properties are required; that containing 36% has the remarkable property of being practically non-expandable when heated up to 350° C., and it is also used in sensitive electrical relays etc., owing to certain of its magnetic properties. Other alloys containing higher quantities of nickel are used because of their exceptional magnetic and mechanical properties.

It might be recalled, in passing, that the steels most resistant to chemical and high temperature attack, referred to in the issue of this JOURNAL for March 11, contain nickel as an essential constituent, while it is unnecessary to remind readers that our present-day motor-car and aeroplane engines are only made possible by the strength and toughness of nickel and nickel-chromium steels.

We are glad we have visited Clydach and seen the various Wiggin Works at Birmingham; we were interested to see so much and learn so much. We have to thank the technical staff for the information they gave us. It is pleasant to meet men who can not only explain scleroscope tests and tell you how many pounds per 100 ft. is represented by 4 S.W.G., but who know also the details of the many and varied uses to which the alloys they are producing can be put.

CONVENTION OF CANADIAN CHEMISTS

Quebec, June 6—9, 1927

Preliminary Programme

Dr. A. E. Macintyre has very kindly furnished the following preliminary programme of the important Convention of Canadian Chemists, which will be held in Quebec from June 6—9:

MONDAY, June 6

9 a.m. Registration Laval University, Central building

10.15 a.m. Technical meeting, Large Hall. Chairman, Dr. A. E. Macintyre.

Report of Secretary, Canadian Council of Society of Chemical Industry.

Address: Chairman Canadian Council.

11.15 a.m. Papers.

1 p.m. Luncheon.—Chairman: Sir George Garneau.

Dr. V. Martin, Mayor of Quebec:—Address of welcome.

An address will also be given on a chemical subject.

3.30 p.m. Garden party at Spencer Wood. Guests of Hon. N. Pérodeau, Lieut. Governor, Quebec.

8 p.m. Public meeting. Chairman, Right Rev. C. Roy, Rector Laval University.

An address is to be arranged.

TUESDAY, June 7.

9.30 a.m. Technical meetings.—Chairman: Dr. George Baril. "Papers."

2.30 p.m. Technical meeting.—Chairman: Dr. Lash Miller. "Papers."

7 p.m. Sail on St. Lawrence to Island of Orleans, Quebec bridge, and view harbour facilities.

WEDNESDAY, June 8.

9.30 a.m. Technical meeting.—Chairman: Dr. Harold Hibbert. "Papers."

1 p.m. Luncheon. Chairman: Hon. George E. Amyot. Address: Chemical subject.

3 p.m. Visit by auto cars to Battlefield Park and points of interest in Quebec, with visit to Montmorency, Ste Anne de Beaupré.

7.30 p.m. Banquet at Chateau Frontenac. Chairman: Mr. J. M. McCarthy.

Guests: Hon. N. Pérodeau, Hon. L. A. Taschereau, Premier of Quebec; Monsignor C. Roy; Hon. E. Lapointe, M.P., Minister of Justice; Hon. L. Cannon, M.P., Solicitor-General; and others.

THURSDAY, June 9.

9.30 a.m. Technical meeting. Chairman: Dr. John S. Bates. "Papers."

Ladies' entertainment.—Monday. Garden party, Spencer Wood.

Tuesday. Tea at Quebec Golf Club.

Tuesday evening. Sail on St. Lawrence.

Wednesday. Auto tour, Quebec to Ste Anne de Beaupré.

Members of the Society of Chemical Industry, American Chemical Societies, and other chemical associations are cordially invited to attend.

CANADIAN PULP AND PAPER INDUSTRY

The Provincial Paper Mills, Ltd., having five plants operating at Port Arthur, Thorold, Mille Roches and Georgetown, Ont., and, until recently, controlled by U.S.A. capitalists, has passed into the hands of Canadian interests. This involves a cash transaction of about \$8,000,000. The majority of the common stock has been purchased for \$135 per share. The company was incorporated in 1920, and the financial report for 1926 showed earnings of 17.4% on common shares, which compares with 13.35% in 1925, and 9.11% in 1924. The company paid dividends amounting to 6% per annum during the past five years, and in 1923 it paid an extra dividend of 1%. The company has extensive timber-limits north of Lake Superior.

The New Brunswick International Paper Company, Ltd. (Subsidiary International of U.S.A.) will commence the erection of a paper mill at Dalhousie, N.B., having an initial daily capacity of 250 tons newsprint, with arrangements for increasing to 500 tons. The company has several mills in New Brunswick, and very large timber-limits in the province and adjacent territory in Quebec. The company is developing the large Grand Falls water power, on the St. John River, and a portion of this will be utilised at Dalhousie.

The first annual report of the St. Maurice Valley Corporation, which covers the thirteen-month period ending December 31, 1926, shows a gross operating profit of \$4,735,856, which is almost four times the amount required for interest charges. Bond, bank and other interest charges totalling \$1,267,833 were deducted, leaving a profit of \$3,468,022. The disposal of the profit was as follows:—Depreciation and depletion reserves, \$1,065,708; preferred dividends, including 7% on St. Maurice Valley Corp., \$563,801; 7% on Belgo-Canadian Paper Company, Ltd., \$572,758; 7% on Canada Paper Company, \$87,500; common dividends to Belgo-Canadian minority stockholders, \$22,836; and \$325,000 transferred to contingent account, left a surplus of \$1,030,418. Fixed assets are valued at \$44,269,227.

SOCIETY OF CHEMICAL INDUSTRY

Annual Meeting, Edinburgh, 1927

PROGRAMME

MONDAY, July 4.

8-10 p.m. The North British Station Hotel—Informal Reception by the Chairman and Committee of the Edinburgh and East of Scotland Section, followed by *Conversazione*.

TUESDAY, July 5.

9.30 a.m. Committee Room, University Union—Council Meeting.

10 a.m. Debating Hall, University Union—Civic Welcome by the Lord Provost of the City of Edinburgh: Welcome on behalf of Edinburgh University by the Vice-Chancellor.

Annual General Meeting of the Society of Chemical Industry (for Members only).

Presentation of the Society's Medal to Lieut.-Col. G. P. Pollitt, D.S.O.

11 a.m. Debating Hall, University Union—Address by the President—Francis H. Carr, Esq., C.B.E.

A panoramic photograph will be taken in the quadrangle of the Medical Buildings, The University, immediately after the President's address.

1.15 p.m. The North British Station Hotel—Luncheon by invitation of the Edinburgh and East of Scotland Section. Representatives of the Edinburgh Town Council, and of the Universities of Edinburgh, St. Andrews, and Aberdeen will be present.

3.30 p.m. Garden Party in the Zoological Park.

8.30 p.m. Palais de Danse—Reception by the President, and Dance.

WEDNESDAY, July 6.

10 a.m. Medical Chemistry Classroom, Medical Buildings, The University.

Joint Meeting with the Bio-Chemical Society—Subject of discussion, "The Physiological and Industrial Aspects of the Chemistry of Carbohydrates."

Papers will be read by:—

(1) Prof. W. N. Haworth, D.Sc., Ph.D. "Structural Relationships in the Carbohydrate Group."

(2) Prof. A. R. Ling, M.Sc., F.I.C. "Recent Advances in our Knowledge of the Polysaccharides."

(3) Mr. C. G. Lambie, M.B., Ch.B., F.R.C.P.E. "The Intermediary Metabolism of Carbohydrates."

(4) Probable paper on "Cellulose from the Industrial Standpoint."

10 a.m. Midwifery Classroom, Medical Buildings, The University. Meeting of the Chemical Engineering Group.

Paper will be read by:—

Mr. J. L. A. Macdonald, D.S.O., D.Sc. "Some Aspects of the Manufacture of Fibrous Cellulose."

to be followed by discussion.

By the kind permission of William Harrison, Esq., LL.B., Chairman of the Inveresk Paper Co., Ltd., and Associated Companies, a section of the film showing the activities of these Companies will be exhibited. This section shows "The Production

of Esparto Paper from the Raw Material to the finished Product."

2 p.m. Visit to Edinburgh Corporation Gas Works, Granton.

2.15 p.m. Visit to University Chemical Laboratories, King's Buildings, Edinburgh.

4 p.m. Reception by invitation of the University Court in the Upper Library Hall, Old University Buildings.

7.15 for 7.30 p.m. The North British Station Hotel—Annual Dinner of the Society. (Tickets 12s. 6d., exclusive of wine.)

THURSDAY, July 7.

10 a.m. Medical Chemistry Classroom, Medical Buildings, The University.

Lecture by the Society's Medallist—Lieut.-Col. G. P. Pollitt, D.S.O.—on "The Development of the Synthetic Nitrogen Industry in Great Britain."

11 a.m. (Same room). Lecture by M. Ernest Fourneau, Pasteur Institute, Paris, on "Chemotherapy in Relation to Tropical Diseases."

12 noon. (Same room). Lecture by Prof. J. Read, University of St. Andrews, on "Natural Sources of Energy in Australia."

11 a.m. Midwifery Classroom, Medical Buildings, The University. Meeting of Fuel Section of the Society—Subject of discussion, "Coal Cleaning."

List of the papers to be read will be supplied later.

2.15 p.m. Meeting of the Fuel Section (*continued*).

2.15 p.m. Visit to the Paper Mills of Messrs James Brown & Co., Ltd., Penicuik.

2.30 p.m. Visit to Castle Mills, Edinburgh, the Works of the North British Rubber Co., Ltd.

8 p.m. City Chambers, Edinburgh—Reception by the Lord Provost and Magistrates of the City of Edinburgh.

FRIDAY, July 8.

Excursions:—

(1) Whole day Excursion to Melrose, Abbotsford, Dryburgh, and Peebles. Tickets, including lunch and tea, 15s.

(2) Afternoon Excursion to Forth Bridge and Inchcolm. This excursion is limited to 90 Tickets, including tea, 6s.

Evening: If a sufficient number of members apply for tickets (8s. each), a dance will be arranged for 8.30 to 1 a.m.

Conducted tours of Old Edinburgh will be arranged for Thursday and Friday.

SATURDAY, July 9.

The following excursions will be arranged if a sufficient number of members apply for tickets:

(1) Gleneagles Golf Course. Tickets 10s., including green fees.

(2) St. Andrews. Railway fare, 7s. 6d.

ACCOMMODATION

No bedrooms are now available in the North British Station Hotel. A list of other hotels was published in **CHEMISTRY AND INDUSTRY** for February 4, 1927, p. 106.

Single room accommodation for both men and women is still available in the University Hostels. Immediate

application for such should be made to the Hon. Secretary of the Edinburgh and East of Scotland Section—Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

CALENDAR OF FORTHCOMING EVENTS

- May 2. INSTITUTION OF THE RUBBER INDUSTRY. *London and District Section*. Special Meeting at the Engineers' Club, Coventry Street, Piccadilly, W., at 8 p.m. "Specifications for rubber goods and the value of performance tests," by J. M. Bierer. Dr. P. Schidrowitz will preside.]
- May 2. SOCIETY OF CHEMICAL INDUSTRY, *Yorkshire Section*. Great Northern Hotel, Leeds, at 7.30 p.m. Annual General Meeting. "Soil formation processes and the foundation of a new subject," by Prof. N. M. Comber
- May 2. SOCIETY OF CHEMICAL INDUSTRY, *London Section*. Annual Meeting. Rooms of the Chemical Society, Burlington House, Piccadilly, W.1, at 8 p.m. "Recent investigations on contact insecticides," by F. Tattersfield and C. T. Gimingham.
- May 3. INSTITUTION OF CIVIL ENGINEERS, Great George Street, Westminster, S.W.1, at 6 p.m. The 33rd James Forrest Lecture. "Some recent services of metallurgy to engineering," by Prof. H. C. H. Carpenter.
- May 4. SOCIETY OF PUBLIC ANALYSTS, Chemical Society's Rooms, Burlington House, Piccadilly, W.1, at 8 p.m. (1) "Investigations into the analytical chemistry of tantalum, niobium and their mineral associates. VII.—The precipitation of tungstic acid by tannin; and VIII.—The separation of tungsten from tantalum and niobium," by Dr. W. R. Schoeller and C. Jahn. (2) "The separation of vanadium and tungsten," by S. G. Clarke. (3) "The determination of moisture by the volatile solvent method," by J. M. Jones and T. McLachlan. (4) "A study of antimony trichloride as a possible quantitative reagent for vitamin A," by F. Wokes and S. G. Willmott. Informal dinner will be held at the Popular Café, 200, Piccadilly, at 6.30 p.m.
- May 4. INSTITUTION OF SANITARY ENGINEERS, Caxton Hall, Westminster, S.W. 1, at 6 p.m. "House refuse collection and disposal," by F. Wilkinson.
- May 5. CHEMICAL SOCIETY. Ordinary Scientific Meeting, Burlington House, Piccadilly, W.1, at 8 p.m. (1) "The nature of the alternating effect in carbon chains. Part XVIII. Mechanism of exhaustive methylation and its relation to anomalous hydrolysis," by W. Hanhart and C. K. Ingold. (2) "The interrelationships of the sulphur acids," by H. Bassett and R. G. Durrant.
- May 6. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual General Meeting. Imperial College of Science and Technology, Kensington, S.W.7. Formal business meeting at 6 p.m. An informal dinner will probably be held at 6.30 p.m., and at about 8 p.m. a paper entitled "Chemical fire extinguishers" will be read by Dr. W. R. Ormandy.
- May 6. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*. Joint meeting with the Fellows of the Chemical Society resident in Manchester and district.
- May 10. INSTITUTION OF CIVIL ENGINEERS. Annual General Meeting. Great George Street, Westminster, S.W.1, at 6 p.m.

CORRESPONDENCE

THE STATUS OF SCIENTIFIC WORKERS

SIR,—In common with other chemists I have recently received an appeal from the National Union of Scientific Workers, issued with a view to extending the membership of that body among qualified scientists, and, by means of a questionnaire, to ascertain the attitude of such workers towards the Union in its present or a modified form.

The following paragraph from the appeal disclaims the strike weapon:—

"Possibly one misconception that seems to be existent should be removed: some non-members still ask whether to join the National Union of Scientific Workers would not mean being called out on strike in certain situations. The strike is not a possible weapon for scientific workers, and the Union has never imagined the possibility of its employment," but obviously leaves the presumption that combination is desired because force of numbers has effective application; though it seems to me that some measure of control over the freedom of action of members is essential, if the fact of union is to mean strength.

Do scientific workers want anything unreasonable? Is professional dignity to descend to collective bargaining? In the long run, is such bargaining ever more effective than education in securing legitimate aims?

I venture to submit my opinion that the only sound, dignified and economic means by which scientific practitioners can enforce the recognition of science, and of their own status, is reasoned yet vigorously insistent propaganda. It is a method which is irresistible, and one which leaves the individual unrestricted. The object of union should be to secure the income necessary for such propaganda.

Yours faithfully,

J. B. WARD

PERSONAL AND OTHER ITEMS

A deputation from Imperial Chemical Industries, Ltd., which includes Sir Alfred Mond and Sir Harry MacGowan, is making a tour of investigation in Germany. They have already inspected the Leuna Nitrogen Works.

Dr. R. H. Pickard, F.R.S., Principal of the Battersea Polytechnic and Director of Research for the British Leather Manufacturers' Research Association, has been appointed Director of Research for the British Cotton Research Association, in succession to the late Dr. A. W. Crossley. Dr. Pickard is a vice-president of the Institute of Chemistry, and is a member of Council of the Chemical Society. He is also on the Councils of the Launderers', Boot and Shoe, and Adhesives Research Associations.

Sir John Russell, Director of the Rothamsted Experimental Station, Major Walter Elliot, Parliamentary Under-Secretary of State for Scotland and chairman of the Research Committee of the Empire Marketing Board, and Dr. J. B. Orr, Director of the Rowett Institute for Research in Animal Nutrition, Aberdeen, are on their way to Palestine to inquire into problems of animal husbandry and dry farming.

Dr. Peter G. Carter, of the Chemistry Research Laboratory, United College, University of St. Andrews, has been appointed to a lectureship in organic chemistry in the University of Sydney.

Prof. Nernst, Prof. W. Ostwald, and Prof. R. Willstätter have been elected honorary members of the American Chemical Society.

We regret to announce the death of Dr. A. Simon, a well-known metallurgist, who had much to do with the practical work of perfecting the use of the cyanide process in South Africa. He had been a member of the Society of Chemical Industry since 1898.

The late Dr. A. W. Crossley, F.R.S., late director of the British Cotton Industry Research Association, left £28,432 with net personalty £25,247.

The Supply of Metallurgists

A shortage of scientifically trained metallurgists would be a very serious matter to our metallurgical industries directly, and indirectly to industry at large. In the *Manchester Guardian Commercial* of April 21, Prof. F. C. Thompson, who occupies the Chair of Metallurgy in Manchester University, discusses the possibility of such a shortage. "The slump in entries of honours courses in metallurgy still persists throughout the country, and it does not require very acute prevision to predict that in three or four years' time, when those now entering will be completing their courses there will be fewer honours graduates than can be placed in positions. . . . In an attempt to discover what is the exact position with regard to the supply of honours metallurgists, a questionnaire was sent round to all the universities of England, Scotland, and Wales, which have honours schools in the subject, together with a certain number of technical colleges of approximately university standing. To those heads of departments who so kindly furnished the information required the writer's cordial thanks are due. All the universities replied to the request. The first point of interest which emerged from a consideration of the replies was the surprisingly large extent to which the surplus resulting from the large immediate post-war entries had been absorbed. A certain number of graduates are engaged on work other than metallurgical, but the number still without posts is almost nil. The supply of really well-trained men is inadequate to the obvious needs of the country. For their own sakes intending students of a scientific turn of mind and preferably, though not necessarily, interested in practical matters, might well consider metallurgy as a possible line of work. The matter is, however, of far more than personal importance. With the continuous diffusion of the metal producing and working industries in all parts of the world, it is inevitable that competition should become ever keener. Countries once importers are now able to supply their own needs, and are even in a position to compete with us. Only the most economic methods of production and the highest attainable class of product are able to withstand this intense competitive pressure, and neither of these will come by instinct. It has not been without interest to note during the past few years the resistance of some firms to the trade conditions, and their ability to do more than keep their heads above water. The development of the aluminium and the

nickel industries in this country, to mention two examples only, have resulted in the employment of relatively very high proportions of university graduates, and it is not a coincidence that severe economic conditions are least felt where highly-trained men are the essential element in the staff."

Gow Lectures

Owing to unforeseen circumstances, the Gow lectures on "The colloid chemistry of the rubber industry," arranged to be given by Dr. E. A. Hauser, at University College, London, in May next, have been postponed. It is hoped to arrange for the lectures to be given towards the end of the year.

Liquid Chlorine in Canada

Recently we published an article, "Liquid Chlorine: Its Manufacture and Uses," by Messrs. J. H. Hubel and D. A. Pritchard (*CHEM. & IND.*, March 18, 1927). In this article it is stated that 65% of the chlorine manufactured in U.S.A. and Canada is consumed by the pulp and paper industry, 22% in the textile industry, 10% in sanitation, and the remaining 3% for all other uses. From further information which has come to hand, we now learn that a considerable change has taken place in the consumption of chlorine, due primarily to the increased production of amyl acetate and ethylene glycol—the former used as a lacquer solvent and the latter as a radiator refrigerant and after nitration for the formation of a non-freezing dynamite.

Due to recent developments, therefore, the above percentage consumption appears as follows:—Pulp and paper industry, 50%; textile industry, 15%; sanitation, 16%; and 19% to all other uses. Of this 19% about 3% is used for chlorobenzene, carbon tetrachloride, hydrochloric acid, etc., the rest being used for amyl acetate, amyl alcohol, and ethylene glycol.

Sodium Sulphate in Canada

Sodium sulphate of Western Canada, its occurrence, uses, and technology, is the title of a report under the authorship of L. Heber Cole, recently issued by the Mines Branch of the Canadian Department of Mines.

Although the occurrence of saline lakes in Western Canada has been known for many years, it was a search for potash during the great war that directed serious attention to their commercial possibilities and led to their examination in detail. These lakes occur in depressions in the morainic drift of Manitoba, Saskatchewan, Alberta, and British Columbia. These deposits consist chiefly of hydrous sodium sulphate (Glauber's salt) with small percentages of magnesium sulphate, sodium chloride, and related salts. Investigations by the Mines Branch show the presence in the 21 deposits examined in detail of over 115,000,000 tons of hydrous salts, mainly sodium sulphate.

In Canada, sodium sulphate, in the form of salt cake, finds its largest use in the pulp and paper industry, and is also employed in the metallurgical, glass, dye, textile and other industries. Upwards of 40,000 tons, mostly imported, is used per annum. Until recently most of the salt cake used in commerce has been produced as a by-product in the manufacture of hydrochloric acid from common salt.

A map of Western Canada accompanying the report shows the location of some 83 occurrences of these

natural deposits. The mineralogical, physical, and chemical characteristics of the several salts are described in separate chapters. The probable mode of origin of the deposits is also discussed. The industrial uses of sodium sulphate in the several industries and the technology of its manufacture are described. A method of examining the extent of individual deposits has been demonstrated, the character of the deposits shown, and the basis laid for the future development of extensive industries. This report (No. 646) is a comprehensive volume of 155 pages, fully illustrated with photographs, drawings and maps. Copies may be obtained by application to the Director, Mines Branch, Department of Mines, Ottawa, Canada.

Soda Lakes in Canada

Natron, natural crystal soda, occurs in considerable quantity in British Columbia, in small, undrained lakes which occupy shallow depressions over the southern portion of the Green Timber plateau, just to the north of Clinton, one of the integral plateaux forming the great interior plateau situated in the south of British Columbia.

According to present knowledge, practically all the 11 soda lakes of commercial importance are situated within an area of about 30 sq. miles. This area is about 10 miles north of Clinton, and is traversed by the Pacific Great Eastern Railway. Most of the lakes are within 1 mile of the railroad, and all except two are within 13 miles. The lakes are small, ranging from 5 to 35 acres in area. The depth of brine in the lakes containing the greater amounts of soda does not exceed $3\frac{1}{2}$ ft. The available tonnage of natron in nine of the lakes examined is, on a preliminary estimate, about 200,000 tons. The largest single deposit contains about 70,000 tons.

In all except two of the lakes the soda is in solution during the greater part of the year, but when the concentrated brine is chilled by the cool autumn weather the soda crystallises out in the form of natron. If the brine were not chilled and concentration by solar evaporation were to continue, the resulting deposit would be the mineral trona, a mixture of the carbonate and bicarbonate. This is the usual form in which soda occurs in natural deposits throughout the world.

The natron deposited each autumn forms in a bed from 3 to 10 in. in thickness over practically the whole of the lake in most cases. It contains as a rule less than 1% of impurities, and is suitable for marketing as sal soda or washing soda. It must be harvested during the autumn or winter, preferably the autumn, for then it is not contaminated with other salts that are deposited later from the brine. With the coming of spring this natron crystal redissolves.

Analyses and further details regarding the material in these lakes are given, under the title "Sodium carbonate in British Columbia," in Section V of Mines Branch Report on Investigations of Mineral Resources, 1921 (No. 642), issued in 1926 by the Department of Mines, Ottawa, Canada.

COMPANY NEWS

LEVER BROTHERS, LTD.

The thirty-third annual general meeting was held on April 21, Mr. Francis D'Arcy Cooper (chairman) presiding. The chairman expressed regret at the losses

through death of Mr. J. H. Barrington, a director of John Barrington & Sons, Ltd., Dublin; Mr. J. Purcell, managing director of Wm. Taylor & Co., Ltd., Edinburgh; Mr. T. J. Davey, a director of J. Kitchen & Sons, Ltd., Australia; and Dr. von Waldkirch, vice-president of the Savonnerie Sunlight. He then briefly reviewed one or two of the associated companies. British Oil & Cake Mills, Ltd., in which the company owned all the ordinary shares, was unable, on account of the coal strike, to give any return on the investment, but conditions had improved, and current trading was showing a satisfactory profit. Results of trading in margarine were satisfactory during last year. Referring to the recent Government report on the marketing of Empire foodstuffs, which contained the following passage: "The question of improving the food value of margarine by the inclusion of ingredients rich in vitamins is one of considerable importance from the point of view of national health. This is a matter to which research could very profitably be directed," the chairman said that research in this direction had been going on in Lever Brothers' laboratories for several years past, and had resulted in the production of a vitamin concentrate which could be readily incorporated in other foodstuffs. The immediate practical result of this discovery had been the placing on the market by their associated company, Planters Foods, Ltd., of a new brand of margarine called "Viking Margarine," which had the nutritive value of the best butter but cost considerably less. The company's turnover for the year was £70,441,000, the decrease from the previous year being due to reduced sales in oils, nuts, or kernels crushed, pressed, or extracted. It represented 1,720,865 tons of goods manufactured or produced by the company and its associated companies. If conditions of trade in this country and all over the world did not become any worse, the profits were likely to show expansion for the current year.

[For the accounts, see CHEMISTRY & INDUSTRY, April 15, 1927, p. 344.]

SOUTH METROPOLITAN GAS CO., LTD.

The agreement between this company and the South Suburban Gas Co., under which the latter company will obtain a bulk supply of gas etc., has received the official approval of the Board of Trade. At an early date stockholders of the South Suburban Gas Co. will be invited to exchange their holding for 6% preference stock of the South Metropolitan Gas Co. For the last three years ordinary stockholders in the South Suburban Co. have received an annual dividend of $6\frac{1}{2}$ %, the statutory dividend being 5%, any addition being dependent upon the sliding scale based on the price of gas; whereas the preference stock of the South Metropolitan Co. pays a fixed dividend of 6%.

ANTON JURGENS' UNITED (MARGARINE) WORKS

A dividend has been recommended on the ordinary shares of 10%. A sum of 1,000,000 guilders is again transferred to reserve for redemption of 6% debentures, 1,566,571 guilders, against nil, is transferred to reserve fund, and 229,873 guilders, against nil, is appropriated for depreciation of factories etc., leaving 8,791,812 guilders to be carried forward, compared with 8,730,065 guilders brought in.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

(Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.)

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4 ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammoniac.—£45—£50 per ton. Chloride of ammonia £37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate.—2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London. 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb., according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic, Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron".—£13 12s. 6d. per ton, f.o.r. London.

Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—1s. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 4s.—4s. 3d. per gal., 60% O.P. Solvent, 4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 10s. per ton.

TAR PRODUCTS

Acid Carbolic.—Crystals.—9½d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 6d.—2s. 8d. per gal. Steady 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 11d.—2s. per gal., ex works in tank wagons.
 Toluene.—90%, 1s. 10d. to 1s. 11d. per gal. Firm. Pure, 1s. 11d.—2s. per gal.
 Xylol.—2s. per gal. Pure, 3s. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 10d.—1s. 11d. per gal. Solvent 95/160, 1s. 6d.—1s. 7d. per gal. Solvent 90/190.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £8 per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—75s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—8s. 6d.—9s. per gal. Nominal. 90/180.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4).—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

CANADIAN INDUSTRIAL DEVELOPMENT

Realizing the growing interest in Great Britain among manufacturers and others in Canada's development opportunities of industrial raw materials, minerals, water powers, forest products, fisheries and other resources, the Canadian Pacific Railway maintains a Development Branch to give reliable information on these subjects and to further assist, through its staff of experts, those interested in investigating these.

This Company also maintains an Industrial Department to assist those interested in establishing Canadian branch factories, in the export and import trade of Canada, or in arranging Canadian agencies and representatives.

You are invited to communicate with The Bureau of Information,

THE CANADIAN PACIFIC RAILWAY COMPANY,
62-65, Charing Cross, London, England.

or

DEPARTMENT OF COLONIZATION AND DEVELOPMENT
CANADIAN PACIFIC RAILWAY COMPANY,
Montreal, Que.

Hello there ! Canada calling !

The Canadian National Railways organise delightful holiday tours to Canada. See Niagara Falls - old Quebec - the Maritime Provinces - and Jasper National Park in the Rocky Mountains, where some of the finest sport in the world—golf, fishing, hunting, boating and bathing, is to be found.

A 7-weeks' accompanied tour-de-luxe costs £190, inclusive ; a five-weeks' holiday for £83. There is also a 3-weeks' trip, with a week first-class in Canada and U.S.A., for £47 5s. return.

For full particulars and free illustrated brochure, apply :

 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb. ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb. Firm and brisk.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum.—1s. 3d. per oz.; 500 oz. lots—1s. per oz.
 Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 5½d.—1s. 6d. per lb. Less 5%. Firm.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 4d.—1s. 5d. per lb. Technical 11½d.—1s. per lb. Both in good demand.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 2½d. per lb. Less 5%. Firm market.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 6d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.
 Bromides.—Ammonium.—2s. 2½d.—2s. 4d. per lb. Potassium.—1s. 9½d.—2s. per lb. Sodium.—2s. 0½d.—2s. 2d. per lb. All spot.
 Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ether meth.—1s. 1d.—1s. 11½d. per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 5d. per gal. f.o.r. makers' works, naked.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb., for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron. Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—22s. per cwt., 112 lb. lots.
 Magnesium Carbonate.—Light Commercial £33 per ton net.
 Magnesium Oxide.—Light Commercial £67 10s. per ton, less 2½%; Heavy Commercial £22 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.L. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 11s.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb. Detached cryst., 14s. 6d. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonat.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin.—3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar) 97s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferrieyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17s. 2d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb. Very limited enquiry.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d. 2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 6s. per ton, d/d consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.
Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
Sulphonal.—7s. 6d. per lb.
Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 3d. per lb.
Thymol, Puriss.—11s. 6d.—12s. per lb., according to quantity.
 Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
Aubepine (ex Anethole).—10s. 6d. per lb.
Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb.
 Amyl Salicylate.—3s. per lb.
Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb.
 Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.
Cinnamic Aldehyde.—Natural, 17s. per lb.
Coumarin.—10s. 6d. per lb.
Citronellol.—14s. 6d. per lb.
Citral.—8s. 3d. per lb.
Ethyl Cinnamate.—10s. per lb.
Ethyl Phthalate.—2s. 9d. per lb.
Eugenol.—9s. 6d. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(ex Bois de Rose) 15s. per lb.—(ex Shui Oil) 10s. 6d. per lb. Linalyl Acetate.—(ex Bois de Rose) 18s. per lb.—(ex Shui Oil) 14s. 6d. per lb.
Methyl Anthranilate.—8s. 6d. per lb.
Methyl Benzoate.—4s. 6d. per lb.
Musk Ketone.—35s. per lb.
Musk Xylol.—8s. 6d. per lb.
Nerolin.—3s. 9d. per lb.
Phenyl Ethyl Acetate.—12s. per lb.
Phenyl Ethyl Alcohol.—10s. 6d. per lb.
Rhodinol.—27s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpineol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb. Good demand.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—12s. per lb.
Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%, 8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure.—6s. per lb.
Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—10s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 17s. 6d. per lb. Japanese, 8s. 3d. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The Complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than June 28th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on May 6th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Bogdandy and Polanyi. Producing finely-distributed mixtures of mutually-insoluble bodies. 10,343. Apr. 14. (Ger., 16.4.26.)

Bohler. Vertical heating furnace. 10,020. Apr. 12. (Fr., 12.4.26.)

Bojner and Pehrson. Apparatus for introducing air etc. into rotary furnaces. 10,034. Apr. 12. (Sweden, 24.4.26.)

British Dyestuffs Corp., Ltd., Hailwood, and Shepherdson. Preparation of finely-divided solids. 9960. Apr. 11.

Calico Printers' Assoc., and Reekie. Steam-heated drying etc. cylinders. 9940. Apr. 11.

Cooper, Henshaw, and Holmes & Co. Treatment of mixtures of vapours etc. 10,224. Apr. 13.

Hartley. Fire extinguishing. 10,360. Apr. 14.

L.-G. Farbenind. Transforming pulverulent substances into small pieces. 9890. Apr. 11. (Ger., 10.4.26.)

Lassen. Producing grinding elements. 10,344. Apr. 14.

McIntyre. Grinding, refining, and mixing machines. 10,230. Apr. 14.

Marks (Polysius). Tube etc. mills. 10,217. Apr. 13.

Reber, Smith, and Woodall Duckham, Ltd. Shaft furnaces etc. 10,193. Apr. 13.

Tcherniac. Joint for apparatus made of glass etc. 10,189. Apr. 13.

I.—Complete Specifications

25,509 (1925). Filtrators, Ltd., and Saks. Emulsion for removing scale from boilers etc. (268,665.)

7897 (1926). Bailey. Furnaces. (249,560.)

12,725 (1926). Maschinenfabr. Simon. Exchange of heat between gases or liquids (252,373.)

22,771 (1926). Schmalenbach. Separating the most volatile constituents of a mixture of liquids. (269,052.)

23,715 (1926). Syracuse Pulveriser Corp. Pulverisers. (258,896.)

24,190 (1926). Wood and Heymann. Drying, heating, or the like apparatus. (269,064.)

25,989 (1926). Muller. Separation of crystals from solutions. (269,068.)

26,592 (1926). Heskamp. Working shaft furnaces. (269,071.)

29,620 (1926). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and Chadder. Fractional distillation. (269,090.)

31,679 (1926). Campbell (Humberston) Roller crushing or grinding mills or machines. (269,104.)

4220 (1927). Scherbaum. Grinding mill (266,009.)

*9636 (1927). Soc. Gen. D'Evaporation. Rotary decanting apparatus. (269,193.)

*9890 (1927). L.-G. Farbenind. Transforming pulverulent substances into uniform small pieces for reaction with gases. (269,209.)

II.—Applications

Barjot. 1300. See VII.

Bataafsche Petroleum Maatsch. Treatment of sludge residues. 10,178. Apr. 13. (Holland, 27.4.26.)

L.-G. Farbenind. Production of unsaturated gaseous hydrocarbons etc. 10,040. Apr. 12. (Ger., 15.4.26.)

Johnson (L.-G. Farbenind.). Preparation of ferric oxide purifiers for gases. 9904. Apr. 11.

Salerni. Distillation of carbonaceous materials. 10,064. Apr. 12.

Sims. Fuels for internal-combustion engines. 10,351. Apr. 14.

Swan, Hunter, & W. Richardson, Ltd., and Young. Treatment of oils or spirits. 10,065. Apr. 12.

II.—Complete Specifications

25,339 (1925). Koppers Co. Gas purification and regenerating sulphided alkaline solutions. (241,221.)

30,814 (1925). Kohlenveredlung Ges. Low-temperature distillation of bituminous substances. (244,456.)

1320 (1926). Hackford, and Hakol, Ltd. Generation of combustible gas. (268,899.)

1699 (1926). Comp. des Mines de Vicoigne, Noeux, et Drocourt. Distillation of coal at low temperatures. (255,411.)

GALLENKAMP'S PRODUCTS

5 IMPORTANT POINTS

IN FAVOUR OF THE

DAVIES' STILL

1. AUTOMATIC WORKING.
2. MAXIMUM RESULTS.
3. EASILY EXAMINED AND CLEANED.
4. COVER AND CONDENSER LIFT OFF.
5. ALL PARTS TINNED AND NO STIFF JOINTS.

THIS

AUTOMATIC WATER DISTILLATION APPARATUS

is made entirely of Copper, heavily Tinned inside, and consisting of three parts:—Boiler, Water and Air-cooled Condenser, and Cover which acts as an Air Condenser and is very convenient for drying dusters, etc.

The steam passes up the centre chamber and immediately comes into contact with the Cover and then passes down between the narrow walls of the Water and Air-cooled Condenser.

SUITABLE FOR

GAS, STEAM or ELECTRIC HEATING, METHYLATED
SPIRIT, PETROLEUM, COAL, COKE or WOOD FUEL.

APPARATUS OF UTILITARIAN VALUE

The Largest Stock of laboratory equipment in Canada

The Fisher Scientific Company, Limited, offers immediate delivery of modern and approved apparatus from the largest stock in Canada.

Each item is designed to better meet a laboratory requirement or to fulfill a need not previously provided for, and is constructed to give the greatest ultimate service per unit of cost.

The Fisher Catalogue

fully describes each article and the methods with which it is used. Moreover, it contains a large fund of information not found in any other book of its kind. Laboratories in Canada are invited to ask for a copy.

N.B.—Repair service and the manufacture of special apparatus to specification are executed in our own glass-blowing and engraving shops on the premises.

*12,462 (1926). Allgem. Ges. f. Chem. Industrie. Apparatus for continuously expelling sulphurous acid from mixtures with oil. (269,118.)

*30,442 (1926). U.S. Industrial Alcohol Co. Non-corrosive alcohol composition. (269,135.)

*9606 (1927). Silica en Ovenbouw Mij. Regenerative coke ovens. (269,188.)

III.—Complete Specification

7946 (1926). Child. Tar or tarry compositions for roadways etc. (268,950.)

IV.—Applications

British Dyestuffs Corp., Ltd., Evans, Hailwood, Harrison, and Jackson. Manufacture of dry preparations of pigment dyes. 9059. Apr. 11.

British Dyestuffs Corp., Ltd., and Hailwood. Manufacture of N-diarylsulphonyl derivatives of arylaminesulphonic acids. 10,090. Apr. 12.

I.-G. Farbenind. Manufacture of diazo-salts etc. 9922. Apr. 11. (Ger., 19.1.25.) Manufacture of diazosulphamic acids of cyclic series. 10,318. Apr. 14. (Ger., 15.4.26.) Manufacture of compounds of aromatic para-diamines with sulphur dioxide. 10,319. Apr. 14. (Ger., 17.4.26.)

Imray (I.-G. Farbenind.). Manufacture of anthrahydroquinone derivatives. 10,190. Apr. 13.

IV. Complete Specifications

21,699 (1925). Woodcock, Drescher, Beckett, Thomas, and Scottish Dyers, Ltd. Dyestuffs. (268,537.)

515 (1926). British Synthetics, Ltd., and Higgins. Manufacture of arylides of orthohydroxy-carboxylic acids and of intermediate products suitable for the preparation of azo dyestuffs. (268,877.)

788 (1926). Brit. Dyestuffs Corp. Ltd., and Tatum. Manufacture of anthraquinone intermediates. (268,891.)

*8146 (1927). I.-G. Farbenind. Manufacture of substituted aromatic sulphonic acids. (269,155.)

*9922 (1927). I.-G. Farbenind. Manufacture of diazo-salts (269,212.)

V.—Applications

British Celanese, Ltd. Products obtained with cellulose derivatives. 10,341. Apr. 14. (U.S., 21.5.26.)

British Celanese, Ltd., Ellis, and Mann. Treatment of cellulose derivatives. 10,342. Apr. 14.

Drepper. Manufacture of cellulose acetate etc. 10,285. Apr. 14.

Kindermann. Filters for production of artificial textile threads. 10,068. Apr. 12.

Nobel's Explosives Co., Ltd., Patterson, and Wilson. Cellulose derivatives. 10,079. Apr. 12.

Oby. 9910. See XIX.

Singer and Wolff. 9903. See XIII.

Verein für Chem. Industrie. Treatment of precipitated acetyl cellulose. 10,028. Apr. 12. (Ger., 15.4.26.)

V.—Complete Specifications

8,959 (1926). Lane and Mellor. Carbonising textile materials. (268,959.)

15,592 (1926). Courtaulds, Ltd., and Diamond. Esterification of cellulose. (269,012.)

18,832 (1926). Merrill. Bleaching pulp. (269,031.)

25,247 (1926). Clavel. Treatment of cellulose derivatives. (269,128.)

30,005 (1927). Friesenhahn. Washing, wetting, and bleaching agents. (269,134.)

30,29 (1927). Rinman. Producing cellulose and paper from straw, asparto, etc. (269,164.)

V.—Applications

Michelle Serre, Ltd., Allott, Hammond, Hatfield, and Skeleton. Dyeing or washing fabrics etc. 10,168. Apr. 13.

Henshilwood and Melville. Treating woven fabrics. 10,231. Apr. 14.

Soc. Chim. des Usines du Rhône, and Theumann. Colouring cellulose esters etc. 10,088. Apr. 12.

VI.—Complete Specifications

632 (1926). I.-G. Farbenind. Dyeing cellulose esters and others. (245,790.)

5760 (1926). Brit. Dyestuffs Corp., Shepherdson, and Davidson. Dyeing acetate silk. (268,933.)

8094 (1926). Brit. Dyestuffs Corp., and Horsfall. Dyeing furs. (268,952.)

*9683 (1927). Brit. Celanese, Ltd. Treatment of yarn packages with liquids. (269,195.)

VII.—Applications

Barjot. Apparatus for separation of hydrogen from hydrogenous mixtures. 10,300. Apr. 14.

Carmichael (I.-G. Farbenind.). Manufacture of chromium oxide etc. 10,070. Apr. 12. Manufacture of alkali nitrates. 10,071. Apr. 12.

I.-G. Farbenind. Recovery of sulphur. 10,039. Apr. 12. (Ger., 16.4.26.)

Mond (I.-G. Farbenind.). Separating phosphorus from gases. 9891. Apr. 11.

Parrish, Snelling, Weight, and South Metropolitan Gas Co. Recovering ammonia from ammoniacal liquor. 10,191. Apr. 13.

Volet. Graphite compositions. 10,024. Apr. 12. (Belg., 29.4.26.)

VII.—Complete Specifications

25,339 (1925). Koppers Co. See II.

30,364 (1925). Leger and Esselmann. Continuous purification of crude carbon disulphide. (254,676.)

18,636 (1926). Johnson (I.-G. Farbenind.). Manufacture of chromic chloride. (269,028.)

21,346 (1926). Nogle. Apparatus for ozonising air and converting it into nitric oxide. (269,046.)

*8892 (1927). I.-G. Farbenind. See X.

*9002 (1927). I.-G. Farbenind. Catalytic production of hydrocyanic acid from formamide. (269,166.)

*9227 (1927). Jacobsson. Dissolving aluminiferous raw materials. (269,174.)

VIII.—Complete Specification

*7888 (1927). Hartford-Empire Co. Glass furnaces. (269,153.)

IX.—Application

Portland-Cementwerk Balingen Ges. Manufacture of acid-proof hydraulic binding-agents. 10,047. Apr. 12. (Ger., 13.4.26.)

IX.—Complete Specifications

438 (1926). Fastig. Burning cement. (268,808.)

886 (1926). Billner. Concrete etc. (268,803.)

7946 (1926). Child. See III.

12,572 (1926). Agerup. Magnesite cement. (268,989.)

X.—Applications

Ashcroft. Separation of minerals etc. 10,169. Apr. 13.

Bosse. Cleaning surfaces of metals in vacuums. 10,084. Apr. 12. (Ger., 7.3.27.)

Brackelsberg. Smelting-furnaces. 10,199. Apr. 13.

(Ger., 9.3.27.)

Coley. Manufacture of zinc. 10,044-5. Apr. 12.

Pfanhauser. Coating articles with metal. 10,302. Apr. 14.

Picard and Sulman. Treatment of antimonial ores etc. 10,214. Apr. 13.

X.—Complete Specifications

11,677-8 (1925). Wills. Producing steel. (245,716-7.)

16,842 (1926). Zinwerke Wilhelmsburg. Treating antimonial ores, especially tin ores. (268,278.)

17,379 (1926). Goldschmidt A.-G. Production of aluminium alloys of high silicon-content. (255,103.)

*29,539 (1926). Stern. Obtaining nickel or ferro-nickel. (269,133.)

*8892 (1927). I.-G. Farbenind. Precipitation of heavy metal from ammoniacal solutions. (269,164.)

*9441 (1927). Gustafsson. Producing metals from oxide ores. (269,179.)

XI. Applications

Dicker (Philips' Gloeilampenfabr.). Electrodes for discharge tubes. 9900. Apr. 11.

Goldschmidt A.-G. Production of aluminium conducting material. 10,301. Apr. 14. (Ger., 19.4.26.)

XI. Complete Specifications

13,898 (1926). Casale. Apparatus for the electrolysis of water. (268,998.)

21,346 (1926). Negle. See VII.

*16,281 3 (1926). Everett. Storage batteries. (269,120—2.)

*9366 (1927). Siemens-Elektrowarme Ges. Insulating-stone for electric furnaces. (269,178.)

XII. Complete Specifications

11,675 (1926). Laffer, and Internat. Zeep-Co. Manufacture of soft soaps. (268,980.)

15,709 (1926). Lechler. Production of permanent emulsions. (254,701.)

XIII. Applications

British Dyestuffs Corp., Ltd., Evans, Hailwood, Harrison, and Jackson. 9959. See IV.

Chem. Fabr. vorm. Schering. Printers' ink. 10,210. Apr. 13. (Ger., 5.5.26.)

Singer and Wolff. Production of cellulose varnishes. 9903. Apr. 11.

Soc. Chim. des Usines du Rhône. Manufacture of powdered plastic material. 10,089. Apr. 12. (Fr., 3.8.26.)

XIII. Complete Specifications

236 (1926). Soc. Chem. Ind. Basle. See XX.

9776 (1926). Ludwigsén. Production of printing-inks. (268,966.)

19,852 (1926). Hick and Hick. Hardening phenol aldehyde condensation products. (269,037.)

XIV.—Complete Specifications

31,246 (1925). Teague. Rubber compositions. (268,853.)

*18,533 (1926). Simplex Wire & Cable Co. Rubber compounds. (269,124.)

*23,346 (1926). Danier. Regeneration of rubber. (269,127.)

*8470 (1927). General Rubber Co. Apparatus for drying rubber latex. (269,157.)

XVI.—Complete Specification

*9731 (1927). Preparation Indus. des Combustibles, and Hoffmann. Manufacture of phosphatic fertilisers. (269,199.)

XVII.—Application

Owen and Stead. Preserving sugar-beets. 10,175. Apr. 13.

XIX.—Applications

Feeny (Vitamin Food Co.). Vitamin foodstuffs. 9912. Apr. 11.

Obry. Extraction of nutritive matter from fibrous vegetable materials. 9910. Apr. 11.

Woo. Manufacture of edible substances. 10,292. Apr. 14. (U.S., 15.4.26.)

XIX.—Complete Specifications

3857 (1926). Jena. Obtaining decomposition products from protein-containing materials. (247,944.)

6442 (1926). Birdseye. Preparing fish foods. (257,222.)

XX.—Applications

Etabl. Poulenc Frères, Mar. ^{patented} organic salts of C-C-dialkyl and arylalkyl barbituric acids. 10,322. Apr. 14. (Fr., 25.5.26.)

Rubber Service Laboratories Co. Manufacture of acetaldehyde. 10,085. Apr. 12. (U.S., 12.4.26.)

XX.—Complete Specifications

28,044 (1925). Dreyfus. Manufacture of acetic acid. (268,845.)

236 (1926). Soc. Chem. Ind. Basle. Converting into soluble form insoluble condensation products of urea or a derivative thereof and formaldehyde. (246,127.)

783 (1926). Johnson (I.-G. Farbenind.). Manufacture of alkyl formates. (268,890.)

18,481 (1926). Hirzel. Production of alkyl and aralkyl resorcinols. (256,225.)

XXIII.—Applications

Moser. Treatment of sludge residues. 10,178. Apr. 13. (Holland, 27.4.26.)

Pulsometer Engineering Co., Ltd. Plant for dealing with sewage. 9966. Apr. 11.

Salemi. Means for destroying micro-organisms. 10,365. Apr. 14.

XXIII.—Complete Specification

25,723 (1925). A.-G. f. Anilin-Fabr. Insecticide. (253,065.)

GENERAL NOTES

Canadian Laboratory Supplies

Nine years ago the need was urgent for a Canadian organisation which could supply industrial chemists and University teachers with their principal requirements in laboratory equipment and chemical reagents, from stock in Canada. Canadian Laboratory Supplies, Ltd., was organised to fill this need. As a company, it is owned and controlled by Canadians, who have developed and set new standards of service in the laboratory supply business in Canada. The company is now in its ninth year, with a concentration of stock at Toronto, drawn from the factories of the largest and best known manufacturers of laboratory apparatus in Europe and the United States. During this period, the company has become the sole or chief Canadian distributing agent for a number of important and well-known lines.

The Needs of the Canadian Chemist

The Fisher Scientific Co., Ltd., of Montreal, claims to be the largest firm in the Dominion which specialises in the supply of the needs of the chemist, and supports its claim by an excellent 640-page catalogue entitled "The Standard Reference Book of the Modern Laboratory," which was published last year. The company maintains a modern glass-blowing shop, where the chemist can have apparatus made to his own design and specification. It also manufactures several specialities such as the Fisher burner, beaker and dish tongs, the Fisher universal gas analyser, the Fisher and Foote optical pyrometer and other useful apparatus.

News from Advertisements

1. Exclusive connections for eastern Canadian market wanted from producers for industrial chemicals used by manufacturers (p. viii).

2. Boots Pure Drug Co., Ltd., invite applications for vacant positions in their research laboratories (p. viii).

3. The Technical College, Cardiff, advertises for a full-time assistant lecturer in chemistry (p. viii).

4. A chief chemist is wanted for an important woollen firm (p. viii).

5. The Salter's Institute of Industrial Chemistry invite applications for a limited number of fellowships and also for a limited number of grants-in-aid (p. viii).

EDITORIAL

Our Review Number

WHENEVER we have one of those prized spare moments which are so infrequently vouchsafed to editors, it gives us no little pleasure to reflect upon the ways of Providence. Providence is a much-maligned lady—we suppose that it is a lady—but she has been remarkably kind in that she has provided mankind with so infinite a diversity of temperaments. No two persons have exactly the same requirements or exactly the same outlook, and thus is really a great blessing. When education became compulsory and universal, it was prophesied that mankind would soon arrive at a dead and monotonous level of equality. True it is that we do not seem to possess such towering pinnacles of genius as in former days, but that is because the valleys have been filled up and the eminences, to be noticed, have really to be mountains, and not mere hills. Whatever be the opinions of the results of universal education, we are not concerned with them here, for we merely wish to point out that general education has not reduced the requirements of mankind, but has rather complicated and increased them. Nowhere is the diversity of these requirements better illustrated than in the unending stream of new books which come from the publishers' presses. We are glad that we have not the task of dealing with general literature, for the publications which relate to chemistry and its allied subjects are quite numerous and important enough. Anyone who is in constant touch with the activities of publishers cannot but be impressed by the activity with which the principles of our science are being everywhere stated over, explained for the beginner, or developed for the practitioner. We are continually being surprised at the revelation of interesting unexplored corners of chemistry. Not one of the least important conclusions that can be drawn from an examination of the new books is that the demand for elementary books of

instruction in chemistry is apparently insatiable. There are books for schools, books in which first principles are combined with history, guides for the budding analyst, first-aid courses for examinations—there is no end to them. Our reviewers seem to think well, on the whole, of these elementary books and so we are brought to the conclusion that, as publishers are business men, and must consider that such books are in demand, therefore chemistry is at last taking its rightful place in the educational syllabus. But these by no means form the bulk of the publications. Amongst general treatises we have, of course, the great work of Mellor on inorganic chemistry which continues to appear: the new edition of Thorpe's Dictionary has been completed, and there have been a couple of inorganic treatises such as those of Ephraim and of Swarts—both highly spoken of—but we do not remember many organic works, other than those of Prof. Cohen, Prof. Noyes, and Dr. Wade. Most noteworthy is the number of publications by specialists. The chemical engineers, aided greatly by the bold Benn, have filled many gaps in the literature, and are promising still more important contributions. In other branches, the chemistry of lignin and cellulose has been tackled; the physical chemists have worked hard in thermodynamics and related subjects. Alexander, Freundlich, Ostwald and others have added to the literature of colloid chemistry; Smithells has dealt with tungsten; there have been several books dealing with special branches of coal-tar chemistry; Parrish and Ogilvie have produced the first part of their work on fertilisers—and so the tale goes on. Our review number contains notices of a number of important books, and the list of recent and forthcoming books contains announcements which will be read with interest. As before, we desire to express our gratitude to our many reviewers, and to those authors who have not yet blossomed into print we would say, "Gather ye publishers while ye may, for old time is still a-flying."

Industrial Research

It is now possible to obtain from His Majesty's Stationery Office, at a cost of ninepence, a 45-page pamphlet giving an account of the work of research associations under the Department of Scientific and Industrial Research. In a very brief preface Lord Balfour states "In the fundamental discoveries of pure science this country, I believe, has taken its full share. About applied science I am not so sure." We think that if we had been called upon for our candid opinion we should have stated that in the fundamental discoveries of pure science this country has taken more than its full share, but that in the application of these discoveries to industry during the last fifty years we have been surpassed by Germany and America in several important instances, and that this is not in the main due to lack of enterprise or faith on the part of our manufacturers. Thirty years ago, and more, this country was so rich that we allowed many opportunities to slip away. Now we are too poor to cope with many other opportunities. Consider the chemical industry; if a really promising development is made, and it seems capable of being a source of profit, what does it involve? Say five or eight years' hard work and an expenditure of £20,000 to £200,000, and then a return of 10% or 12%, or perhaps not so much, on the capital spent. How many chemical firms in this country can afford to spend such a sum of money? If we exclude the gas companies and the oil companies, and a few others which are not truly chemical manufacturers as we commonly use the phrase, we shall find, since the amalgamation, probably only one firm, the I.C.I., with enough financial resources to undertake such a task. The I.C.I., like other recent amalgamations, has its hands full with internal problems at the moment, and until these have been settled and the new mechanism has been thoroughly tuned up there will not be a great amount of superfluous energy available for such external problems as new developments. Although we differ in the wording of a few phrases from the authors of the preface and the account, in the main we agree with them entirely, and we recommend our readers to read the whole pamphlet and think about it. Many instances are given of savings effected as the result of co-operative or State-aided research. There is an interesting account of research in the leather industry resulting, *inter alia*, in showing that the efficacy of liming is not due to the activity of bacteria or enzymes. The work of the various research associations has resulted in the employment of many more scientific men, principally chemists, in the industries concerned. On the whole, the account we refer to is both interesting and encouraging; there are many industries in which important results can be obtained at comparatively small cost; in the chemical industry the problems are both large and expensive.

The Cambridge University Appointments Board

Several methods have been tried for choosing candidates for a vacant post. The apprenticeship system was almost universal in the Middle Ages, but has now fallen somewhat out of fashion; this system is, perhaps,

really part of an educational system rather than a mechanism of choice. The usual modern methods of choosing likely candidates have been (i) influence, (ii) money, (iii) examinations. None of these is good; probably the examination system, bad as it is, is better than the other two methods. The examination system is bad because, as a rule, it is no indication of the candidate's abilities except his or her ability to give written answers to questions without reference to books—an ability which is not greatly used in after life. It is a test, and probably a fairly reliable test, of the candidate's knowledge of the academic side, rather than the industrial side, of a particular science, art, or study. If we attach undue importance to an examination as a test of a grown-up person's fitness for a particular post, we shall find the examination system dangerous and harmful; if we remember its proper limitations, it should be convenient and even useful. Those people who have not merely examined candidates, but have for three or four years taught them as well, who have seen them at play as well as at work, have watched them stand serene at Fenner's and come forth by twos and threes from the broad tower of Trinity, from the green gate of Caius—those people, at least, have a fairly good opportunity of knowing far more about a candidate's capacity than any mere examiner. We are not surprised that the work of the Cambridge University Appointments Board has been successful, that it has grown in volume and importance, and that its recommendations are esteemed by first-rate judges. The Cambridge Board was established twenty-five years ago; it comprises men chosen by the Senate, men chosen by the colleges, and men chosen from industry and commerce. It has included many well-known Cambridge dons, and such men as Mr. Owen Hugh Smith, Mr. John Hugh Smith, Sir Robert Hadfield, Mr. Roscoe Brunner, Sir Arthur Pease, Lord Ashfield, Sir William Mather, Sir Thomas Wardle, and the Hon. Geoffrey Hope Morley. Chemistry is at the moment rather poorly represented on the Board. The Board's report, just issued, speaks highly of the services of the Secretary, Mr. H. A. Roberts, and gives a number of interesting particulars of the work of the Board during the last twenty-five years. One sentence is specially worthy of note: "While the Board think it of the greatest importance to the prosperity of the country that the right type of graduate should find an opening in industry or commerce, they have never suggested that all, or even most, graduates are suitable for this particular purpose." About 1200 B.A. degrees are taken every year at Cambridge; about 400 appointments are obtained every year through the Board. The report gives us the impression that the Board does good work and does it well. About three-fifths of the graduates who enter their names on the appointments register obtain appointments through the Board. This appears to us to be about a proper proportion for one of the old universities. After all, the true test is not one of statistics, it is this: if you have tried one of the Cambridge Board recommendations, will you repeat the experiment and urge your friends to do the same? The fact that the number of appointments has gone up fairly steadily from 100 a year to 400 a year appears to be satisfactory.

REVIEWS

EXERCISES IN GENERAL CHEMISTRY AND QUALITATIVE ANALYSIS. By HORACE G. DEMING and SAUL B. ARENSON. Second edition, revised. Pp. xii + 282. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1926. Price 9s.

This book conforms in order of subject-matter with the second edition of Deming's *General Chemistry*, but it may be used as a practical companion to any modern text-book. The purpose of the authors is to provide a series of exercises, both qualitative and quantitative, which shall lead the beginner steadily on to the acquirement of a sound knowledge of general principles, rather than of a host of disconnected facts of chemistry.

The table of contents shows simple exercises in the following, among other subjects: manipulation, laws of gases and of chemical combination, water and solutions, acids, bases, and salts, hydrolysis, valency, oxidation and reduction, the ionic theory, reaction velocity, colloids, metals, electro-chemistry, catalysis. Some of the common gases are prepared, but there is no effort at completeness; e.g., sulphur dioxide and the oxides of nitrogen, and even carbon dioxide are prepared only incidentally. There are also a few preparations of inorganic salts, and these are followed by qualitative analysis, the purpose of which "is not to get through a certain number of known and unknowns, but to learn chemistry." Consequently, much attention is paid here to procedure and principles, and there are omissions which are to be made good by reference to more advanced text-books. The phosphate separation, for example, is deliberately omitted, and the treatment of acidic radicals is very brief. At the end of each section of the book there are lists of questions which are provocative of thought.

If the purpose of learning chemistry is to become acquainted with the principles of the science rather than to qualify for an examination, to gain an insight into scientific method rather than a detached knowledge of scientific facts, to learn how to tackle a scientific problem rather than to be versed in analytical routine; then it is difficult to think that any better method of procedure could be devised than that set forth in this book. Therefore, all instructors in chemistry who are not slaves to an examination syllabus should get the book, and then earnestly determine how much of its teaching they can make their own.

R. M. CAVEN

SECOND YEAR COLLEGE CHEMISTRY. By Prof. W. H. CHAPIN. Second edition, revised. Pp. xiii + 366. New York: John Wiley & Sons, Inc.; London: Chapman and Hall, Ltd., 1926. Price 15s.

This book was first published in 1922, and for the second edition the chapter on atomic structure has been entirely re-written, whilst a new chapter on colloids has been added. The subject-matter includes the following topics: atomic and molecular theories, valency, periodic law, radioactivity, atomic structure,

properties of solutions, ionisation, indicators, homogeneous, heterogeneous, and complex equilibrium, electro-chemistry, colloids. Exercises follow each chapter.

"Principles are more important than facts and methods," says the author; hence the whole of the second-year chemistry course is devoted to principles. The book is full of the modern spirit of physical chemistry, and appears to be above detailed criticism; the reviewer, therefore, has the more agreeable task of considering whether its contents are adequate and suitable for a second-year course in chemistry. Here the question arises: if this is the second-year course, what are the first and third-year courses; or otherwise, where, and to what extent, is descriptive chemistry to be dealt with in a student's career? This is a question fundamentally important to the teacher of chemistry to-day. Lecture courses are not capable of indefinite expansion; indeed, owing to the growth of the subject, students are in danger of being lecture-ridden. There can be no doubt in the mind of the philosophic teacher that instruction along the lines of this book is desirable, if not imperative: for this goes farther in satisfying the intellectual desires of the student than the rehearsal of facts about the elements, however skilfully these facts may be woven into a parti-coloured pattern. Yet the chemist must know his elements; so what is to be done? That is the question which results from meditation upon a valuable and stimulating book.

Meanwhile, the book will certainly be used on account of its intrinsic merits.

R. M. C.

AN INTRODUCTION TO CHEMISTRY. By C. G. VERNON, M.A., B.Sc. Pp. 276. London: George Harrap & Co., Ltd., 1926. Price 4s. 6d.

This little book introduces chemistry from an historical standpoint in a way which the author claims has not been used before. All the great things in chemistry, from the beginnings of knowledge to the molecular theory, are quickly sketched; then follow short chapters on sulphur, phosphorus, oxides, peroxides and hydroxides, salts, coal, silica and glass, modern manufactures, and more recent chemistry. This occupies 180 pages, and the rest is devoted to practical work, also set historically. The earlier chapters are entirely historical; then the stream of history dries up, and the reader finds himself browsing on the fertile plains of the modern chemical world. Brief questions follow each chapter, including some, of which the following is typical: "Write an imaginary letter from Priestley, giving an account of the discovery of dephlogisticated air."

The total amount of chemical information in the book is not large, but this is a virtue rather than a fault in an introduction to chemistry. The author's style is clear and attractive, and there are some interesting portraits and other pictures. The information seems accurate, and, in the modern part, up to date. The following strange equation appears, however, on p. 149:

The reviewer has read the book with much pleasure, and congratulates the author on the freshness of his treatment, and the success of his achievement. The book is certainly to be recommended as an attractive and stimulating introduction to chemical science.

R. M. C.

AN ELEMENTARY CHEMISTRY. By E. J. HOLMYARD, M.A., M.Sc. Pp. 424. London: Edward Arnold & Co. Price 5s.

This elementary book is intended for boys and girls who wish to know something about chemistry. It is brightly and pleasantly written, and grown-up people have been known to read it through more than once because they liked it. It contains a sufficient number of facts and relevant explanations to form a useful introduction to the science. As might be expected, the historical side is not ignored. The book is well illustrated. The reviewer has tried hard to think of suggestions for the improvement of the book, but so far in vain. It is the best book of elementary chemistry that has been written of its kind, for its special purpose and with its special character, and the author is to be heartily congratulated on it. Even learned people might read it and find something either new to them or more clearly explained than is usual.

PRACTICAL ORGANIC CHEMISTRY. By I. V. HOPPER, Ph.D., A.R.C.S.I., and W. M. GUMMING, D.Sc. Pp. xii + 115. London: Blackie and Son, Ltd., 1926. Price 4s. net.

This little volume on practical organic chemistry is intended specially for students of pharmacy taking the chemists' and druggists' qualifying examination of the Pharmaceutical Society. Each experiment, which is of a simple character, is prefaced by a brief theoretical discussion of the class of compounds which it is intended to illustrate. The order follows the usual arrangement of most text-books: the aliphatic and aromatic compounds being grouped together. The descriptions and drawings are for the most part clear and concise, but call for no special comment.

There is a chapter near the end which deals with the identification of organic compounds and one containing tests for the commoner organic acids and alkaloids.

I am doubtful if it is desirable to bore a cork half-way from both ends, as advocated by the authors. My own experience is that one rarely forms a straight, smooth hole.

I should also like to suggest that, on the principle of prevention being better than cure, the authors should give, not only a method for loosening tight stoppers, but one for obviating the process by smearing a thin coating of vaseline or grease on the stopper before the apparatus is laid aside.

J. B. COHEN

ORGANIC CHEMISTRY FOR THE LABORATORY. By Prof. W. A. NOYES, Ph.D. Fifth edition, revised and enlarged. Pp. xiv + 329. Easton, Pa.: The Chemical Publishing Co., 1926. Price: \$4.00.

That this is the fifth edition since 1897, and the third since 1916, is a fact which appraises the book. Thirteen of the sixteen chapters of the book are con-

cerned with the preparation of organic compounds, each chapter being devoted to one class of compound. Valuable features of this section are the summary of the methods available for the preparation of each type of compound, and the full references to the literature that appear at the beginning of each chapter. Further, the characteristic reactions of each compound are described after each preparation, so that an intelligent student who has worked through a selected series of preparations will find the short chapter at the end of the book, dealing with the qualitative examination of organic compounds, all that is necessary to enable him to take up what is perhaps the most important part of his training as a student of organic chemistry, namely, the examination of substances with the view of relegating each to its respective class and verifying his report by the preparation of characteristic derivatives.

In the preface to this new edition it is stated that the author has found the determination of carbon with the use of the Parr total carbon apparatus to be both rapid and convenient, and has therefore included the directions for this method. Unfortunately, such directions are rendered quite unintelligible by the fact that the figure (Fig. 6) to which the detailed description is referred depicts only a small part of the whole apparatus, and, moreover, the letters in the figure do not tally with those in the text.

M. A. WHITELEY

HYDROGEN ION CONCENTRATION. By L. MICHAELIS, M.D. Vol. I. Principles of the Theory. Authorised translation from the second revised and enlarged German edition, by Dr. W. A. PERLZWEIG, xiv + 299. London: Baillière, Tindall & 1926. Price 22s. 6d.

In this translation of Dr. Michaelis' well-known monograph (1922), opportunity has been taken to include more recent advances, such as the quinhydrone electrode of Bilhmann and co-workers (1921-1924), and the activity theory of ionisation of G. N. Lewis, Bjerrum and Debye. The object of the book, as indicated in one of the prefaces, is "to present to biological readers the general theoretical principles upon a broad foundation before the details of their application are dealt with."

The first part deals with electrolytic equilibria and ion concentrations, including the cases of amphoteric electrolytes, difficultly soluble acids, hydrolysed salts and "strong" electrolytes. The title of the second part is "the ions, particularly the hydrogen ions, as sources of electric potential differences." This includes, of course, both potentials at electrodes, and those at liquid-liquid and liquid-solid interfaces such as diffusion potentials and adsorption potentials. The latter class has been more fully treated—the author has been tempted to make a somewhat comprehensive survey of such phenomena as electro-endosmosis and electrophoresis.

It would be difficult to maintain that any book of the class can be absolutely "sans tache," as claimed by the publishers (*e.g.*, quinhydrone electrode is indexed at p. 177 instead of p. 171). Still, the misprints are at a minimum. A purist in the English language might object to a few awkward constructions, *e.g.*, "the type of always completely dissociated electrolytes." These are, however, trifles. The book is admirable as an introduction

tion to be read straight through, or as a work of reference for the comprehension of the broad outlines of theories which are becoming every year a more essential part of the equipment of the worker in biochemistry and allied branches. The book has a pleasing appearance, but the pages are rather loosely inserted.

E. B. R. PRIDEAUX

PHYSICO-CHEMICAL GEOLOGY. By R. H. RASTALL, Sc.D., F.G.S. Pp. vii+248. London: Arnold & Co., 1927. Price 15s.

Dr. Rastall set himself a difficult task when he essayed a book which would adequately cover the ground comprised in his title. This is fully realised in the preface; nevertheless he has produced a work full of interest, of undoubted value, and one covering a remarkable amount of ground. The twelve chapters are somewhat unequally balanced, the amount of elementary exposition in the earlier part curtailing the space available for more advanced matter. Thus, colloids in geology are dismissed in eight pages, and in the otherwise excellent chapter on metamorphism the important subject of metasomatism receives less than its due share. There are very good chapters on isomorphism, igneous rocks and rock weathering, but these, like the whole book, would be of greater value were the references to literature augmented, particularly with references to more recent work. This applies especially to the discussion of differentiation in igneous magmas, and to the chapter on ore-deposits. The book is clearly written, printed on comfortable type, remarkably free from errors, and has a good general index.

H. W. GREENWOOD

THE EVOLUTION AND DEVELOPMENT OF THE QUANTUM THEORY. By N. M. BLIGH, A.R.C.Sc., A.I.C. With a foreword by Professor Max Planck. Pp. 112. London: Edward Arnold & Co., 1926. Price 9s.

Natural phenomena, formerly studied by observing the behaviour of matter in bulk, have been found to conform satisfactorily in most cases to general laws founded on statistical mechanics, *e.g.*, the kinetic theory of gases, and the law of mass action. Naturally, with each development of our knowledge of atomic structure, the tendency to refer the properties of matter in bulk to those of the individual atoms has been more and more manifested. Difficulties arose whenever classical mechanics was applied to considerations involving the relationship of energy to matter, the former being too general to apply to matter which is discontinuous. The quantum theory, however, supplies the required restrictions.

The theory was originally conceived to explain the various phenomena of heat radiation, and was, therefore, of greatest interest to physicists; its application now to photo-electric effects, to atomic heats, and to atomic structure compels the interest of chemists.

Chemists who have felt the need of an ordered account of the origin and development of the quantum theory will welcome Mr. Bligh's book on the subject. In it they will find a systematic treatment from the origin of the theory to the radiation experiments to its application in Bohr's interpretation of the chemical elements. The book is lucidly written, and can confidently be recommended to chemists.

Some of the mathematical proofs, however, leave

something to be desired, notably on pp. 21 and 32. Their reading is made the harder by the rather large number of errors that have escaped the proof corrections. A list of those errors which were noted by the reviewer has been forwarded to the publisher; but it might save some confusion on the part of readers of the book if it were here pointed out that the second law of thermodynamics is correctly given by equation 159 on p. 79, and not as given at the beginning of p. 21; that the dimensions of Planck's constant are correctly given on p. 53 and incorrectly on p. 55; that it is the expression $M/(M + m)$ on p. 92 and not M that is slightly greater for helium than it is for hydrogen; and that equation 156, called the minimum work equation, is more correctly called the maximum work equation, as the author has done on the following page.

JOHN A. CRANSTON

CATALYSIS IN THEORY AND PRACTICE. By F. K. RIDEAL and H. S. TAYLOR. Second edition. Pp. xv + 516. London: Macmillan & Co., Ltd., 1926. Price 20s.

The second edition of this standard textbook is presented in the same admirable setting as the original work, the volume being of convenient shape and size, clearly printed on good paper. The chemical formulæ and mathematical symbols are well set out, adding considerably to the ease with which the contents may be assimilated.

The book is only about twenty pages longer than in its first edition, showing that a considerable amount of matter previously contained must have been omitted in order to provide space for the large quantity of new data which have been introduced. This is also reflected in the table of contents: for example, the chapter on ferments and enzymes has disappeared, this subject being treated partly under "Hydration and hydrolysis" and partly in the new chapter on "Colloidal catalysts."

Again, the more exclusively theoretical treatment of the subject, which formerly occupied 74 pages, now takes up 158 pages, including the chapters on "Promoters, mixed, supported and protected catalysts" and on "Catalyst poisons and the inhibition of homogeneous chemical reactions."

The tendency of the volume is therefore in the direction of theory rather than of practice, and this is unavoidable, and indeed desirable, in order to obtain the necessary conspectus of the diverse theoretical investigations carried out in recent years by numerous bands of workers. These have gone far to make clear much of what was formerly obscure and even mysterious in the behaviour of catalytic agents, and the broad, yet detailed and critical, survey of the results and views of the whole group given by Rideal and Taylor is of great value. One might, indeed, go further and point out that an intimate acquaintance with the results of modern theoretical work in this field, as summed up in this book, is indispensable to any technologist who is concerned with the industrial application of a process in which catalysis plays a part.

The chief technical applications of catalysis are included as before, but as already indicated the space available for the practical side of the subject is distinctly less than it was. It is an open question whether, in the circumstances, it might have been as well not to attempt

so complete a survey of this side, and to confine attention to selected instances of the more important industrial employment of catalysts. For example, it seems to the writer that much of the matter in the chapters on catalysis in organic, analytical and electro-chemistry, and some of that in "Catalysis by radiant energy" could better have been spared in order to devote more space to such phases as the production of ammonia, urea, methyl alcohol and the higher alcohols, or the industrial applications of enzyme action. The last-named subject is a matter which, taking a long view, is probably as important as all the other technical aspects of catalytic action put together.

Taylor's picture of the composite catalytic surface (*Proc. Roy. Soc.*, 1925, **108A**, 105), whether completely warranted by the existing data or not, is probably a sufficiently close approximation to have justified its inclusion at greater length on pp. 75-79: it affords a clearer view of the modern theory to the non-mathematical mind, and completes the more general treatment as given in the present volume (in the reference to Rideal's discussion on the same subject, given on p. 115 (footnote) as *Counsel Solcay*, 1926, the date should be 1925).

In the section on technical processes of fat-hydrogenation, no reference is made to the important continuous process and compact nickel catalyst devised by Bolton and Lush.

This second edition of Rideal and Taylor's monograph should receive as warm a welcome as the original, and it is to be hoped that in due course the authors will be called upon to produce a further edition, and that they will then revise the theoretical data available by that time as thoroughly and broadly as in the present volume.

T. P. HILDITCH

THE PROBLEM OF PHYSICO-CHEMICAL PERIODICITY. By E. S. HEDGES, M.Sc., Ph.D., and J. E. MYERS, O.B.E., D.Sc. Pp. 95. London: Edward Arnold & Co., 1926. Price: 7s. 6d.

To the chemically curious this volume will certainly supply many hours of interesting reading, for in it the authors have collected together most industriously the scattered and numerous records of periodicity in chemical and physical actions. To the chemist who deals in molecules in large quantities an ordered rate of change is always expected, but in dealing with individual atoms some species of discontinuity in action is to be anticipated. It would, however, be rash to interpret any periodic action in mass to quantised processes, for in general some simpler explanation is forthcoming. Thus the periodic bands formed by lycopodium in the well-known Kundt's tube experiment and the periodic dissolution in acids of metals which are capable of being rendered passive are readily interpreted on simple physical and chemical considerations.

It is somewhat significant that since Bray's periodic reaction between hydrogen peroxide and iodine has been shown not to be truly periodic in character, there is no established case of periodic reaction in homogeneous systems: they are all confined to interfaces.

The two properties of interfaces which appear to be of special significance in periodic action are, firstly, their

powers of adsorption, which, at any rate, appear to offer a simple interpretation of many periodic properties in space, e.g., the Liesegang rings; and, secondly, that reactions at interfaces in many cases spread out from nuclei or active patches over the whole interface, i.e., at the contact of dissimilar superficial phases, a property which may readily give rise to periodicity in time.

The chief criticism which the reviewer has to make about the volume as a whole is that the authors lean somewhat too heavily on the mystery of periodic actions. The principle of mysterious pulsations as the *fons et origo* of all chemical reaction is one which should not lightly be adopted as a basic hypothesis by those who are desirous of examining the processes of nature in detail. In spite of this, the authors have themselves contributed no small addition to our knowledge of pulsating action, and one hopes that they will continue to do so, so that eventually the various factors may be disentangled, properly labelled, and their relative importance in the sequence of events evaluated. The volume is undoubtedly a stimulating one to read, and is excellently printed and bound.

E. K. R.

KOLLOIDCHEMISCHE TECHNOLOGIE. EIN HANDBUCH KOLLOIDCHEMISCHEN BETRACHTUNGSWEISE IN DER CHEMISCHEN INDUSTRIE UND TECHNIK. Edited by Dr. E. Liesegang, with the assistance of numerous collaborators. Lieferung I. Pp. 80. Lieferung 2. Pp. 81-160. Dresden and Leipzig. Th. Steinkopff, 1926. Price (subscription): 5 g m. each.

As its advertisement says, this work interests all who have to do with colloid material, and to-day their name is legion. The work, of which only the first two parts have been received, is to consist of some 800 to 1000 pages, with numerous illustrations, diagrams, etc., and is divided into a theoretical and a technical part. The first two numbers cover about one-half of the theoretical portion, and deal with the preparation of inorganic colloidal solutions, following the Svedberg's "Methoden" in arrangement, with a few references to literature since the last edition of that work, but well documented as regards patent literature. Then comes a section on the colloid mill and its technical applications, all too short for its purpose, and dealing almost exclusively with the Plauson mill. This is followed by an excellent review of ultrafiltration and dialysis, which manages to cover a large field in but little space. Electro-osmosis next claims attention and the very interesting and suggestive account of its applications will be of value to many colloid workers. The last subject dealt with in the second part is the viscosity of colloidal solutions, and here too much space is devoted to a general discussion of viscosity and instruments, with the result that specific subjects of great technical importance receive but scanty attention. For example, glue and gelatin are dismissed in half a page. This may well foreshadow a general criticism to which books of this class must, almost of necessity, be subject, namely inadequacy. Against this we have the boldness of the attempt to deal with the whole field of colloid technology and theory in 1000 pages. Frankly, the work cannot be exhaustive; it does not claim to be, but it is, so far, eminently readable, exceedingly stimulat-

ing and suggestive, and as a general reference work pointing to original sources definitely valuable. It is well printed, with clear illustrations and good diagrams, and is an exceedingly cheap compendium on colloid technology, and worthy to be received and kept by every colloid chemist.

H. W. GREENWOOD

KOLLOIDCHEMIE. By Dr. E. LIESEGANG. Pp. xii+176.

Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe, edited by Dr. E. Liesegang.

Vol. VI. Second revised and enlarged edition.

Dresden and Leipzig: Theodor Steinkopff, 1926.

Price, paper, 8 m.; bound, 9.50 m.

A previous report on colloid chemistry by the same author covered the period from 1914 to 1922, during the greater part of which German readers were cut off from foreign scientific publications. The present—second—edition surveys, in addition, the literature up to about the middle of the current year. It serves approximately the same purpose as the reports published by the British Association Colloids Committee, but while the latter were compiled by a large number of contributors dealing with different aspects of the subject, Dr. Liesegang takes the whole of it for his province. This is an enterprise which now exceeds the powers of one individual, and differences in competence and in predilections naturally show themselves, even in the brief abstracts to which considerations of space confine the author. Still, they always give a sufficient idea of the contents to enable the student to decide which of them he has to read *in extenso*, and this is no small task to have accomplished for something like 1200 references. Their completeness is also remarkable; in those portions of the subject in which the reviewer can claim an exhaustive knowledge of the literature he has not been able to detect any omissions, and only one or two minor inaccuracies. The volume will be of the greatest use to all who have to consult the ever growing and still widely-scattered literature of colloids.

A satisfactory index is even more important in a work of this description than in most others, and both the subject-matter and the name index are unusually good. An engaging feature of the latter is that a name like "MacBain" appears under "M," whereas most German authors (or index makers) take the patronymic prefix for a Christian name and list this author under "B."

E. HATSCHEK

GAS AND GASES. By Prof. R. M. CAVEN, D.Sc. Pp. viii+256. London: Williams & Norgate, Ltd., 1926. Price 2s.

After a generation or more of science teaching in schools, there ought to be a considerable public interested in the chemical facts of every-day life if these are readably presented. The publishers of the Home University Library—which has an established reputation—evidently share this belief. In the chemistry of "Gas and Gases" they have selected a topic which should appeal to every enquiring reader, because the subject is indeed vital to every living creature. In Prof. Caven they have found an author who evidently has the faculty of presenting the subject in a way likely

to satisfy an interested and intelligent layman. He has, however, given the basic facts of the properties of gases so completely and concisely that the student of chemistry also might read this book with profit. The two chapters on the atmosphere and the rôle of its various constituents in the cycle of life make delightful reading, and portray the true romance of chemistry. It is only when dealing with some applications of chemistry that the book invites criticism. The author would find it difficult to substantiate the statement (p. 136) that a gas fire warms the air by convection. Convection from an ordinary gas fire plays only a minor part. Again, what evidence is there that the stuffiness of an atmosphere is due to "noxious organic emanations" (p. 181)? Statements in the chapter on combustion and explosion would merit discussion, but exhaustive treatment cannot be demanded in such a work. The book, however, remains an excellent popular exposition of chemistry, and well worthy of its place among its companion volumes.

H. J. HODSMAN

EXPLOSIVE REACTIONS IN GASEOUS MEDIA. A GENERAL DISCUSSION HELD BY THE FARADAY SOCIETY. JUNE, 1926. Reprinted from the Transactions of the Faraday Society. Vol. XXII. October, 1926. Pp. 252—375. London: The Faraday Society, 1926. Price 10s.

Few fields of research offer such excellent opportunities for the co-operation of the chemist with the physicist on one hand, and with the engineer on the other, as that which deals with explosive reactions in gaseous media. Their mutual interests are well shown in this report of the general discussion held by the Faraday Society last June. The subject is essentially a chemical one, but the experimental investigation is largely physical, as it deals with the measurement of uniform movement and detonation speeds of flame, of the pressures produced on explosion or temperatures of ignition and with the effect on these of radiation and ionisation, each of which is considered in one or more of the papers read at the meeting. The applications, also considered, appeal most particularly to the engineer concerned with the efficient utilisation of gaseous explosions in internal combustion engines, or with their prevention in coal mines.

An admirable introductory survey of the subject by Dr. Garner gives an idea of its complexity. In particular does this apply to the study of the part played in gaseous explosions by the "chemical kinetics" of the reactions. The possibility that ionisation may play an important part in such reactions is attractive, but receives little support from the papers read, in so far as ignition or the propagation of flame or detonation are concerned.

The question of "pinking" in internal combustion engines and its prevention receives considerable attention, and it is to be regretted that Dr. Midgley's survey of the subject was not available. The explanation of pinking and of the remarkable "anti-pinking" effect of certain compounds is still to be found. It would seem that the general use of the term "detonation" as synonymous with pinking is a questionable one, more especially as Professor Dixon and Messrs. Egerton and Gates have

shown that anti-pinking compounds have no apparent effect on the setting up or on the speed of detonation in gas mixtures.

The report will be found indispensable to those desirous of keeping in touch with the present trend of research on problems of gaseous combustion. W. P.

I.—TREATISE ON THERMODYNAMICS. By DR. MAX PLANCK. Third English edition, translated from the seventh German edition by DR. A. OGG. Pp. xiv + 297. London: Longmans, Green & Co., Ltd., 1927. Price 15s. net.

II.—THERMODYNAMICS AND CHEMISTRY. By F. H. MACDOUGALL, M.A., Ph.D. Second edition. Pp. vii + 414. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1926. Price 27s. 6d. net.

I.—It is gratifying to find that there is still a definite, if restricted demand for an English translation of this well-known textbook, in spite of the numerous treatises on thermodynamics by other writers who owe it an acknowledged debt. The diversity of applications of the science have, of course, been dealt with in much greater detail elsewhere. The permanent value of Planck's work, however, lies in his lucid method of presentation of the fundamental principles of thermodynamic theory. In re-reading the introduction and "proof" to the Second Law, it is hard to appreciate the distaste which chemists, up till recent years, have evinced for entropy as a thermodynamic tool. Entropy is the fundamental function from which the other thermodynamic functions are derived, and the conception, as introduced by Planck, presents no difficulties. Further, there is no question that the worker in thermodynamics will find his labours greatly lightened if he is not restricted to think in terms of free energy only, but has the ability to choose always the function best suited to the problem in hand.

The present translation differs from its predecessor chiefly in the inclusion of a chapter on "Absolute value of entropy," and of short sections on the theory of the Joule Thomson effect and Ghosh's theory of strong electrolytes. It is a pity that the translator does not indicate that Ghosh's theory, which was very favourably received in Germany, is now discredited, and mention the more satisfactory treatments of Milner and Debye and Hückel, the latter of which appeared after the publication of the last German edition (1922). The translation is on the whole admirable, but the first few chapters contain minor faults (cf. §§10, 32, 67) which might have been rectified in this new edition. It is also unfortunate for the reader who is familiar with the German edition of Planck that his symbols S and ϕ for entropy and characteristic function are here needlessly changed to ϕ and ψ respectively.

II.—This advanced text-book, which offers one of the best intensive courses in chemical thermodynamics at present in circulation, is based in large part on Planck as a model. The fundamentals of the subject are presented in the same clear manner and somewhat more fully. After this, the usual physical and chemical applications are given in detail, in some cases, it must be remarked, with rather more of mathematics and less

of chemistry than will appeal to every reader. Notable features of the book are the relatively extensive treatment of the phase rule, the selection of problems appended to each chapter, and the numerous tables of useful data scattered through the book.

"Since the publication of the first edition of this work, a remarkable contribution to our knowledge of solutions of electrolytes has been made by Debye and Hückel. The author has endeavoured to give an adequate presentation of their views in Chapters XVI and XVII . . ." We expect a critical account of current views on the problem of strong electrolytes in a book of this kind, and it is a pity that considerations of space have apparently restricted the author in some cases to bare statements of results, which of themselves will convey little to the student. The last chapter has been rewritten to give a more balanced account of the Nernst heat theorem and the third law of thermodynamics. If it is necessary here to give even brief mention of Planck's treatment of the equilibrium between radiation and matter, the author might have done better than present it in the form—continuous absorption, discontinuous emission—which physicists never favoured, and which Planck himself has abandoned. The list of errata is rather large, considering that many of these are carried over uncorrected from the first edition. A. McKEOWN

DIE FERMENTE UND IHRE WIRKUNGEN. By PROF. CARL OPPENHEIMER. With a section on Physical Chemistry and Kinetics by DR. R. KUHN. Fifth edition, completely rewritten. Nos. IX—XIII. Leipzig: G. Thieme, 1926. Price: No. IX, 17.40 r.m.; No. X, 17.10 r.m.; No. XI, 17.10 m.; No. XII, 17.45 m.; No. XIII, 19 m.

With the issue of the above-mentioned five parts, this work reaches completion; it covers (including the author and subject-matter index) 2,039 pages. We have already dealt with the first eight numbers (cp. this JOURNAL, 1921, 880 R; 1926, 146 R).

Now that we have the complete treatise before us, it is desirable in the first place to review it as a whole. Although the pagination is continuous, it is divided into two volumes. The first volume (775 pages) deals, in a general manner, with the chemistry of enzymes, the kinetics of their actions, and the biology of the subject. It concludes with a special portion concerned with specific enzymes:—The hydrolases-esterases, carbohydrases, and the nucleases. The subject matter of the second volume deals with amidases and amino-acidases, proteases, including peptidases, tryptases, pepsinases, chymase, thrombase, and anti-thrombase, e.g., hirudin, a hæmolytic enzyme. The saponins are well known to possess hæmolytic properties, but as these have not been definitely traced to an enzyme, that is probably the reason why reference to them is omitted in the book.

In the concluding portion of the treatise, which is that with which we are at present specially concerned, the text is devoted to a description of those enzymes and their action by which oxidations and reductions are effected in the organism. The general name assigned by the author to this group is desmolases. He remarks that they may be regarded as direct metabolic enzymes.

as they promote the special processes whereby the organism is able to obtain energy from ingested food, or from its own tissues.

The first group to be discussed is that comprising the so-called autoxidisable substances which undergo oxidation by giving up hydrogen to an acceptor of that element, or which undergo reduction by accepting hydrogen from a donator of that element. The work carried out in this field is discussed in detail, including that of Traube, Bach, Wieland, Palladin, Kastle, Schulze, Bourquelot on oxidases, dehydrases, and respiratory pigments, as well as that of Hopkins on glutathione.

Under oxidation by atmospheric oxygen, the peroxide theory of Traube and of Engler and Bach is discussed, and in this connexion attention is called to the influence of the presence of heavy metals—some stimulating, some inhibiting. The extensive work which has been carried out on animal and plant respiration, both aerobic and anaerobic, is treated exhaustively. A discussion of the *zymases*, which include the enzyme of alcoholic fermentation, covers 291 pages of text. Some space is devoted to modern views of the structure of the different fermentable sugars, but as this portion of the text was published before the appearance of Haworth's papers, the latest views on the subject are not included. It is treated from the chemical and biological standpoints, and some points concerning vitamins and, notably, insulin, are included. Much space is devoted to the different dehydrases which have been described, as well as to the chromo-dehydrases and chromo-oxydases. The text concludes with a chapter on the chemistry of the catalases. An index of authors, giving the titles of original papers, and an index of subjects, are useful features.

Having now made a survey of the complete treatise, we can reiterate the opinion previously expressed of its great value as the most complete contribution yet published to the literature of a subject of far-reaching importance both to pure and applied science.

ARTHUR R. LING

LEHRBUCH DER ENZYME. CHEMISTRY, PHYSICAL CHEMISTRY AND BIOLOGY. By Prof. CARL OPPENHEIMER in collaboration with Dr. R. KUHN. Pp. ix+660. Leipzig: G. Thieme, 1927. Price, paper 33 m., bound 36 m.

This work is a shortened edition of the authors' treatise "Die Fermente," designed specially as a textbook. On these lines a better connected account of the subject might have been presented than was possible in the more extended work. The subject matter has been brought up to date, but the number of references to original papers has been curtailed considerably. The names of authors responsible for the observations cited in the text are given in some cases without the references.

The first 206 pages deal generally with the chemistry and kinetics of enzymes. The remainder of the work is a special part which is concerned with specific enzymes, the arrangement and nomenclature being the same as adopted in the larger work. There is a very good subject matter index, but an author index is omitted.

Prof. Oppenheimer and Dr. Kuhn have certainly rendered a great service to students of that branch of biochemistry with which their book deals, but we

think, bearing in mind the fact that the larger treatise on the subject has only just reached completion, that the present book would have been more useful had it been reduced to one-third its size and the text (which is identical with that of the larger treatise with the incision of portions) recast.

ARTHUR R. LING

CORROSION OF METALS. By U. R. EVANS, M.A. Second edition. Pp. xvi + 259. London: E. Arnold & Co., 1926. Price 15s. net.

From the time of the first scientific work on corrosion until the older electro-chemical theory was propounded, the theory of this most important subject fluctuated almost from year to year. With the electro-chemical theory, ground appeared to have been touched at last and, in a way, this was true. The difficulties inherent in this simple hypothesis, however, soon became apparent, but the intensive research carried out in recent years has led at last to a theoretical position where the whole subject is presented as one unit which is sufficiently comprehensive to explain a very wide range of fact. The modern electro-chemical theory is, of necessity, more complicated than the older one, but it is, at the same time, sufficiently simple to be presented in some detail, adequate for all practical needs, in a book of 250 pages.

In this development the author himself has played an outstanding part, which clearly fits him to deal authoritatively with his subject, but which, fortunately, has not prevented him from presenting it in a simple and extremely lucid manner. That a second edition should be called for in two years shows at once what interest is taken in corrosion itself and the satisfactory manner in which its present position is dealt with. The new edition, although so soon needed after the appearance of the first, contains a considerable amount of new, or newly presented, matter, and is an achievement of which any author might legitimately be proud. The book has a really practical trend, as well as being a truly scientific treatment of the subject, and can be unreservedly recommended to all those chemists, engineers or metallurgists, who are called upon to deal with the subject.

F. C. T.

LA FABRICATION DES FERRO-ALLIAGES. By AIMÉ COUTAGNE. *Grandes Encyclopédies Industrielles, Encyclopédie Minière et Métallurgique*, published under the direction of L. Guillet. Pp. 650. Paris: Librairie J.-B. Baillière et Fils, 1924. Price 60 fr.

This volume, one of those forming the new *Encyclopédie Minière et Métallurgique*, published under the editorship of M. L. Guillet, deals with ferro-alloys, metallic carbides and silicides, and the "special" metals manganese, chromium, tungsten, vanadium, uranium, titanium, and zirconium.

The author has presented his subject in the following manner:—(1) Raw materials (ores and electrodes). (2) Generalities on the metals, carbides and silicides. Constitution, properties, etc. (3) Process of manufacture in combustion furnaces (blast furnace, crucibles, etc.). (4) Process of manufacture in electric furnaces, including (a) generalities on electric furnaces, (b) processes in which the use of the electric furnace is possible

but not necessary, (c) processes in which the use of the electric furnace is indispensable, and (d) the consumption of electric energy in the manufacture of the chief electro-thermic products. (5) Processes of manufacture based upon reduction other than by means of carbon. (6) Electrolytic processes. (7) Industrial applications.

As is frequently the case in this class of work, the chapters dealing with sources of the raw material are the weakest, much of the information being out of date, and consequently misleading. Generally speaking, the purely technical matter is excellent, and is presented in a readable form, easy for reference.

METALLURGY OF CAST IRON. By J. E. HURST. Pp. xvi + 311. London: Sir I. Pitman & Sons, Ltd., 1926. Price 15s. net.

The author states in his preface that the object of his book is to furnish foundrymen with an account of the features governing the constitution and properties of grey cast iron, and he has attained his object very successfully. His book is a scientific treatise on grey cast iron, and it is significant of the progress that has been made within recent years in the scientific knowledge of the principles of foundry practice that he finds it unnecessary to enter upon any detailed description of metallographic methods or any elaborate definition of metallographic terminology, such as would have been indispensable only relatively few years ago in addressing the average ironfounder.

The work commences with a discussion of the iron-carbon alloys and their constitution, paying special attention to the formation of graphite, and next considers the influence upon the resulting cast iron of the more important accessory constituents—namely, silicon, sulphur, manganese and phosphorus. A chapter is devoted to the effect of the rarer constituents—or, as the author terms them, "special elements"—and another to the influence of dissolved or occluded gases. After going through the more strictly chemical portion of the subject, the physics of cast iron are attacked, and the next few chapters deal with the effect of heat treatment, the volume changes, the growth and the shrinkage of cast iron. Then comes a series of chapters on the mechanical and physical properties of cast iron, and finally, a couple of chapters are devoted to a discussion of special mixtures, including semi-steel, and to the use of metal moulds in the foundry.

It is, perhaps, to be regretted that the author has confined himself so strictly to the subject of grey cast iron, in consequence of which the production of chilled castings in which a portion of the iron is white, receives but scant attention. Upon the whole, the work is well done and the treatment of the subject is adequate; that the chapters on the iron-carbon alloys are not quite as clear as might be wished is due less to the fault of the author than to the extreme complexity of the subject and to the want of agreement amongst the leading authorities as to the interpretation to be assigned to the enormous mass of observed facts. The only really weak chapter in the book is the introductory chapter on the production of pig iron, which is distinctly on a lower level of accuracy than the rest of the work. To quote but one example, the author gives a table of analyses of

typical iron ores, one column of which purports to represent the composition of "Swedish ores"; undoubtedly there does exist some Swedish ore having the analysis there given, but it cannot be said to represent the composition of the bulk of the ore produced in Sweden; it would have been just as reasonable to quote an analysis of a Cumberland hematite under the caption of "English ore"! Fortunately, however, this introductory chapter will not greatly concern the ironfounder, to whom the work is addressed, and who will find in this book a well-compiled mass of information constituting the scientific basis of his important industry.

COAL AND ALLIED SUBJECTS. COMPENDIUM II OF BULLETINS ELEVEN TO SIXTEEN ISSUED BY THE LANCASHIRE AND CHESHIRE COAL RESEARCH ASSOCIATION. By N. SIMPKIN, M.Sc., and F. S. SINNATT, M.B.E., M.Sc., with collaborators. London: H. F. & G. Witherby, 1926. Price 15s.

This is the second volume of these collected bulletins. The first paper, on stone dusting in mines, is a very useful summary of work that has been done in determining the influence, on the explosive power of coal dust and air mixtures, of the fineness of the dust; the volatile content, moisture, ash, and carbonates in the coal; the quantity of dust in the air; the oxygen content of the air; and the velocity of the wave or current necessary to raise the dust into the air. It goes on to summarise information as to the mechanical nature—fineness, sharpness of particle, etc., and composition of the various stone dusts that have been used for admixture, and indicates that, whether in efficiency as a preventive of explosion or in effect on the respiratory organs of those working in the roads, the mechanical nature has much the greater influence, and that the composition is, indeed, almost a matter of indifference.

The second bulletin, on the chemical composition of pyrites from coal, is largely an account of the authors' own investigations into the occurrence of pyrites in coal, and the nature of its oxidation products and course of the oxidation, and forms a small storehouse of facts not easily obtained elsewhere. The bibliography at the end is very full, and those working at this subject will be grateful to the authors for it.

The third bulletin, on the determination of carbon monoxide in vitiated air, is a description of an addition to the ordinary Haldane gas analysis apparatus, of an iodine pentoxide tube and associated steam bath, for the determination of small percentages of carbon monoxide; it also describes the apparatus devised by Graham and by Sinnatt for the determination of minute percentages in a large volume of gas. Presumably the bulletin is intended for those not already skilled in such work, for the methods of using the apparatus for the whole of the analyses are described in very great detail. A diagram of the apparatus, instead of the actual photograph shown, would have made the description easier to follow.

The fourth bulletin, on the preparation of thin sections of coal for the microscope, is an excellent résumé by the Messrs. Lomax of their patient work on this subject. The processes are described in great detail, and the bulletin will be very helpful to anyone wishing to prepare

sections, though the authors do not gloss over the difficulties of, or minimise the long practice needed to acquire skill in, these preparations.

The fifth bulletin is concerned with the melting point of coal ash. Reference is made to the work of other observers in this field, and detailed description is given of the authors' apparatus for determining melting points on a small quantity of ash. Many results are given, and the conclusion is arrived at that no definite connexion between composition and melting point can be traced, and that direct determination must be resorted to for knowledge of the melting point of any given sample.

The sixth bulletin is a general account of boiler feed waters, corrosion, and formation of scale; and of softening processes and plants. The causes of scale formation, and the chemical reactions on which softening processes are based, are quite well described, and the bulletin forms a useful practical introduction to the subject. The phraseology, though, might well be subjected to revision in many places. To speak of a water "containing" degrees of hardness seems to me objectionable; and though the authors do not like the definition of temporary hardness as that which disappears on boiling, and would substitute "that due to carbonates," yet they define permanent hardness as the "residual" hardness. "More universal" can hardly be justified; and the authors say that the "capacity of a plant cannot be increased," when they mean that the plant cannot be worked beyond its capacity. Again we are told that if necessity demands it, a certain plant should be *chosen*: obviously, if there is necessity there can be no choice. Many similar lapses occur, not only in this bulletin, but throughout—for instance, the book is described on the title page as a compendium: it is not a compendium, but a collection—and the trouble is, that this looseness of phraseology tends to make the reader suspect (and, indeed, tends to produce) looseness of thought. A little more care over expression would have been very well spent.

These bulletins justify their publication. Some contain original matter; others are useful compends, and probably come into the hands, largely, of those to whom their contents are useful, but who would not know where else to look for the information. Misprints are few—the name Drechsel is misspelt, and on page 33 of the sixth bulletin 0.02 should, I think, be 0.2. There is a very ambiguous sentence, ending page 17 and beginning page 18 of the third bulletin, which calls for revision in any reprint. The repetition of the title of the bulletin at the bottom of each page, close to the text, worried me a good deal; but this may be a personal idiosyncrasy.

J. T. DUNN

THE CHEMISTRY OF WOOD. By L. F. HAWLEY and L. E. WISE. American Chemical Society Monograph Series. Pp. 334. New York. The Chemical Catalog Co., Inc., 1926. Price \$6.00.

This work is one of the series of monographs undertaken by the American Chemical Society (1919) on a programme comprising some 60 sectional subjects. The authors have justified selection for their particular task in producing a volume which is something more than a bibliography.

Representing distinguished centres of research, they have given us at first hand a critical record of the investigations of the Forest Products Laboratory (Madison) and other American schools which group around this very live institution, collated in due perspective with those of the German and Scandinavian workers in this field. In entering upon their task they state in an opening paragraph: "We have worked unhampered by trails or precedents" in a "pioneering adventure." This declaration of independence, in its exuberant freshness, early stimulates the anticipation of a student disciplined in old-world traditions, further raised by the authors' statement, on the following page, that their two chapters on lignin are presented "with a certain degree of temerity but without apology"—this after a description of their critical method of exhausting the literature of a subject "befogged in speculation and bandied to and fro in an endless series of polemics and debates."

Expectations, however, thus raised are damped by the statement, "We are dealing with the chemistry of wood, a product that has already been elaborated by the plant. Our subject, then, is static not dynamic." May we suggest, as a disappointed reader, that this delimitation takes us from the "Chemistry of Wood" to the "Chemistry of Timber." Here we have a shortened *exposé* of the dilemma, in terms of its material horns with or upon which the authors struggle in their introduction. It appears in yet another form, "We have consistently attempted to differentiate between *speculation* and *investigation*," which we convert into the usually accepted form of the antithesis, "theory and actuality." The authors fail to see that in ruling out hypothesis they, in this case, rule out reality. Since Wood is the Tree, and the tree is not a mere assemblage of carbon compounds, but a structural complex of organised products, it is clear that resolution of the complex by laboratory methods involves the ever-present problem of the relationship of the products of resolution to the original, as to one another; this must be considered, and can only be discussed in terms of what the authors describe as "speculation," i.e., theory. In effect they repeatedly in the text depart from the limitation of their formal disclaimer to discuss speculative essays on the constitution of cellulose and lignin.

But, for the patient attention of the present reader, and the more useful information of the prospective student, we shorten our criticism into a highly appreciative commendation of the main text, with a reference to "Die Chemie des Lignins," by Walter Fuchs, recently reviewed in this JOURNAL, which successfully grapples with the science of the subject *sans phrase*, and supplies a clear exposition of those aspects which the present work confuses.

The book will be widely adopted as an indispensable work of reference, since it represents a critical selection of the records of all the important investigations of wood substance (ligno-cellulose) and associated secondary products in genetic relationship. The main divisions of the subject-matter are the following: "Chemical Components of Wood"; "Proximate and Summative Analysis of Wood"; "Decomposition of Wood"; and "Wood as Industrial Material."

It is to be suggested to the authors that in the next edition of the work the introduction should set forth, in text-book terms, what is commonly accepted as our exact knowledge of cellulose, lignone and inferentially ligno-cellulose. The relatively brief space required for this *exposé* would add cogency to their contention that in this field it is especially necessary to discriminate between "speculation and investigation," or rather between agenda and acta.

C. F. CROSS

THE CHEMISTRY OF CELLULOSE AND WOOD. By A. W. SCHORGER, Ph.D. Pp. xiv+596. London: McGraw-Hill Publishing Co., Ltd., 1926. Price 30s.

This work is the fruit or rather harvest of a ripe experience, and, to judge from the records, of devoted personal work in this field. In the first sentence of the preface it claims to "cover completely the scientific and empirical data available on the chemistry of wood." This claim and the reputation of the author will commend his achievement for appreciative reception by the large and increasing body of chemists engaged in the scientific-technical development of "cellulose." From a critical reading of the text the claim can be confirmed and the commendation emphasised.

Your reviewer's working experience of nearly 50 years shapes a number of critical points upon which to judge the fulness and accuracy of the text, and the text more than satisfies such critical examination.

In sequence of chapters the first four deal with wood formation, structure, proximate composition, with a special account of lignin and lignification, and colour reactions by which identified; the next six chapters develop the subject of "Cellulose," dealing with hemi-celluloses, the typical celluloses of cotton and wood, the modifications included under "Gelatinisation" and by interaction with oxidants and acids. Chapter 10 deals with the conversion of celluloses to sugars, and Chapter 11 with various interactions of wood substances with reagents.

After these follow pulping processes (12), destructive distillation (13), bacterial and fungoid attack (14), animal digestion (15). The concluding chapter describes in detail some 40 laboratory methods and processes of determining proximate components of mixtures and ultimate constituent groups of individuals comprised in the field connoted by the title of the work.

It is our next duty to make certain critical reflections, the first of which is that writers of books on these subjects should be aware that their subject matter tends to the "disperse," in evident correlation with a primary characteristic of the object matters. Cellulose as subject, or objectively as a form of matter, confers apparent solidity upon a large, even multiple proportion of water. Now our brother chemists of the definitely systematised sections of the science are disciplined in a literature marked by a highly concentrated, even crystallised, form of expression.

These are the characteristics of "Beilstein." Our familiarity with this text, however, induces forgetfulness of the "genial" labours involved in the elaboration of such a work. If authors in the cellulose field were mindful of this model they would not merely correct and check the present diffuse expansion of our sectional

literature, but would clear the vision of research workers, many of whom implicitly confess that they "cannot see the wood for the trees." Thus the present author evades the task of laying a ground plan conforming with the logic of the science, trusting to an empirical classification of subject matter to ensure coherent exposition. As an illustration, Chapter 9, "Action of Acids on Cellulose," ranges from the "hydrocellulose" degradations to the synthetic ester reactions; these are polar opposites and a section which appears to unite the underlying conceptions confuses rather than elucidates. There is a chapter (No. 7) under the heading "Gelatinised Cellulose," dealing exclusively with cellulose-water interactions and effects. The application to these of the terms "hydrate" and "hydration" is ruled out after discussion, in favour of a word merely descriptive of an external manifestation of intermediate effect, i.e., of dispersion. Now there is no ascertainable break, e.g., in the hydration effects from that of "hygroscopic moisture" through the mercerisation phase, to that represented by the gelatinised xanthate and viscose; the conversion of wood pulp to "Pergamyn" is continuous, and a function of the conditions of beating. In dealing with these the author makes repeated use of the rejected term "hydration," with the apology of the inverted commas, which produces the effect of ceremonial dress qualified by a coloured necktie.

But "Gelatinisation" is equally characteristic of what we may describe, in following the argument, as cellulose dehydrates, the esters of the nitrate type, the properties of which are dominated by the unresolved complex. On the author's plan these derivatives are inappropriately treated, as stated, in a mixed company—aristocrats with poor relations—and they are left out of what should be a comprehensive treatment of dispersoid phenomena.

Similarly in the chapter on oxycellulose the empirical "viewpoint" is preferred with the result of a record of investigations in time sequence—excellent history, but confusing the modern student in his search for the underlying and essential factors.

A further and last reflection is based upon a statement of critical general import in the preface: "The vast number of organic compounds has been largely produced from simple chemicals by synthesis. The research was prosecuted on the basis of chance and probability, and was not hampered by knowledge of an existing sample which had to be duplicated or torn apart." Through the obscurity of these misused terms and aided by the context, we discern, though dimly, the author's intention to contrast the basis and discipline of systematic chemistry with those of the section comprising cellulose and lignin, but with the apparent result of inverting the accepted view. In the first place, the latter are "organic" compounds, as so distinguished from the "vast number of carbon compounds" of the systematic science. And in respect of the contrast of research method, it is the order of progress in the systematic science to "tear apart" or rather methodically to dissect an existing sample, to duplicate it, but beyond this in thus verifying its constitution to confirm and extend theory, the dominating pursuit, particularly ruling out the factors of chance and probability.

Contrariwise any student interested in the philosophy of the subject will discern a notable element of chance in the historical evolution of the chemistry of cellulose and wood; also the influence of probability, periodically yielding to necessity as the mother of invention, but under rigorous birth control and with very discriminating selection of father.

These reflections are not intended to prejudice the reception of a book reflecting the industry and competency of the author—but rather to point the way to another which shall better fulfil the exacting demands of students to whom Beilstein is a Bible. C. F. CROSS

THE PAPER MILL CHEMIST. By HENRY P. STEVENS, M.A.
Third revised Edition. Pp. ix + 317. London:
Ernest Benn, Ltd., 1926. Price 10s. 6d.

This useful book is very well known, and the present writer believes that it has been and still is much appreciated by chemists and others concerned with the chemistry and technology of the pulp, paper-making and stationery trades. It first appeared in 1908, and a second revised and enlarged edition followed in 1919. We have now the third revised edition under review.

Apart from an enlargement in the size of the pages, the general lay-out of the volume is exactly the same as that of its predecessor of 1919, even to the total number of pages. The size of the original volume was decidedly convenient for slipping into the pocket when one required it for reference whilst engaged in the factory, and, consequently, one is disposed to be just a trifle critical of the wisdom of the change which has been made, especially as there would seem to be no practical advantage gained by the alteration, the disposition of the letterpress and the illustrations being quite the same.

A fairly careful comparison of the two editions has been made, and one is not a little surprised to find that, with one exception on page 172, where, in a brief footnote, Sanders' alternative method of titrating bisulphite liquor is given, new material is non-existent. Considering the activities of the various technical associations attached to the industry in this country, Canada, U.S.A., Germany, etc., it is somewhat disappointing that some new data of sufficient importance and value to be incorporated in a book such as this have not been gleaned from the published work of the past seven years. A good deal of space has rightly been given to the analysis of sulphite liquors, but a similar treatment of sulphate liquor is wanting. Some brief consideration might have been given to the smelting furnace for converting the salt cake to sulphide of soda, to the more modern method of washing wood pulp in the diffuser, and so forth. One, of course, recognises that the publication is not intended to be a complete handbook in the true sense of the word, and that the author is, no doubt, strictly confined to certain limits as to the size of his volume; but, after all, these are matters of no little interest to British readers, and it is not to be forgotten that the book is also for sale on the American Continent. For this latter reason one considers that the American gallon and the short ton should be mentioned in the chapter on weights and measures, as well as the conversion figures for

"grammes per litre to lbs. per cubic foot," and *vice versa*, factors which are continually required in practical mill work.

A few minor errors might just be mentioned in conclusion. The formula Na_2CO_3 on page 68, line 26, is obviously a printer's error. On page 24, Table IX, the printing of the names of the chemicals has been badly done, and the footnotes on pages 297 and 299 should be brought up to date. J. T. STRACHAN

CHEMISCHE TECHNOLOGIE DER ORGANISCHEN VERBINDUNGEN. Edited by Dr. R. O. HERZOG. Second new and enlarged edition. Pp. xii + 997. Heidelberg: Carl Winter, 1927. Price, paper 66 m., bound 70 m.

The object of this book, as stated in the preface, is to give a coherent and readable account of the methods and materials pertaining to the chemical technology of organic compounds, but it is rather doubtful whether this object has been attained. Some sections are clear and pleasantly readable, but others, from their very nature, are bound to be somewhat of the dictionary type. The task of making a work of nearly a thousand large pages readable and attractive to the general student is bound to be almost a superhuman one. On the other hand, it is obvious that a full and encyclopædic account of such a wide field would extend far beyond the limits of one volume—even a large one such as this. For this reason, it is not surprising to find that many sections are far too short and inadequate to be of much help to the technical chemist, and in almost every case the information is considerably less detailed than that in the corresponding sections of Ullmann's *Enzyklopädie*.

Subject to these reservations, the book can be recommended as being sound and accurate as far as the reviewer has been able to judge. It is well printed and copiously illustrated, and contains many large-size folding drawings and plans of plant and factory lay-out. The first section of the book is divided into the following subsections:—tar and bitumen; oils, fats, and waxes; resins and rubber; carbohydrates; fermentation industries; proteins (tanning, glue and gelatin, milk and its products). The second includes subsections on:—coal tar dyes (including ink); essential oils and perfumes; pharmaceutical products; explosives; photographic preparations (including photographic paper etc.); special preparations, including organic acids, solvents, acetylene and its products, and formaldehyde. The third section is devoted to the chemical technology of textiles, and is, perhaps, the most detailed in the book. It includes dyeing, bleaching, mercerisation, loading, printing, chemical cleaning, etc.

In a work of this size, by so many different authors, there is bound to be a good deal of difference of treatment, some sections being far better than others. Although very free from actual errors, the severe compression of certain sections often gives a false perspective which may prove nearly as misleading as actual error. One of the weakest sections of the book is that dealing with pharmaceutical products, which occupies only 29 pages, and is so compressed as to be of very little value. Insulin, for example, is dismissed in five and a half lines, and the

bald statement that the pancreas used for its preparation must be fresh is almost misleading in its lack of emphasis. The whole important subject of organic arsenic and antimony compounds is compressed into twenty-seven and a half lines, and no mention at all is made of the important work of British scientists on derivatives of ergot, adrenaline, and other important substances. The section dealing with essential oils and synthetic perfumes is also very meagre. The section devoted to carbohydrates includes chapters on celluloid and artificial silk, but the 13 pages allotted to the latter are somewhat inadequate, in view of its importance at the present time. Some cross-reference should be made to this chapter in the section on textiles. Amongst the better parts of the book, mention may be made of those on linoleum and on the products derived from acetylene. The latter, though very brief, is clearly written, and has an excellent diagrammatic scheme of the industry. It is surprising that the important subjects of low-temperature carbonisation and hydrogenation of coal are ignored. The book concludes with a section on the subject of effluents and their purification. The importance of this troublesome question is generally not sufficiently recognised in technical literature, and the inclusion of this section is therefore very welcome.

PERCY MAY

DAS KALKBRENNEN MIT BESONDERER BERÜCKSICHTIGUNG DES SCHACHTOFENS MIT MISCHFEUERUNG UND DIE GEWINNUNG VON KOHLENSÄUREHALTIGEN GASEN. By BERTHOLD BLOCK. Second enlarged edition. Pp. xii + 512. Leipzig: Otto Spamer. 1924. Price: paper, 25 g.m.; bound, 27-50 g.m.

The whole subject of lime burning is treated comprehensively in this book, both from the theoretical and practical standpoints. An enumeration of all the points discussed would occupy too much space, but the scope of the book can be gathered from the following summary.

The opening sections contain a few statistics and an outline of the most important applications of lime, which, so far as quantity is concerned, are in building, metallurgy, agriculture and the chemical industries. The chemical and physical processes involved in lime burning are clearly stated. Throughout the book the author keeps prominently in view the division of the process into three periods, viz. "pre-heating," "burning" and "cooling," and the practical detail incorporated may be exemplified by the fact that several graphs are given showing the relation between the size of the lumps of raw limestone on the one hand and the duration of burning and the maximum temperature attained on the other. In order fully to appreciate the subject of fuel consumption, this is calculated first for an "ideal lime-kiln" from thermochemical data and the distribution of the total heat over the preheating, burning and cooling periods is traced. In the following 100 pages the use of various classes of solid, liquid and gaseous fuels is discussed, and even the question of burning lime by electricity is touched upon. Here again the practical aspect is not lost sight of, for data are given showing the size of the lumps of coke that can be used in shaft kilns to secure economical and efficient burning. Nearly 40 pages are devoted to the description and testing of the refractory linings for kilns, and mention of the aluminous

product, "dynamidon," is evidence that the section is well up to date, and the practical character of the information is illustrated by the explanation of the right and wrong way of laying blocks of quartz-schist.

Although the principles embodied in rotary-, ring-, and tunnel-kilns have been applied to lime-burning, the old form of shaft-kiln appears to hold the predominant place still for economy both in fuel and labour. The well-known method of charging these with alternate layers of raw material and fuel is referred to by the author as "mischfeuerung," though others prefer different terms, such as "schichtfeuer." Details of the construction of kilns are given, and also an interesting account of experiments the author has made on "layer formation" by means of a model kiln, using small pieces of marble, some of which were coloured red. In discussing the application of the waste gases, it is pointed out that when these are used in sulphur recovery they must be free from oxygen, as in the Chance process, which, by the way, is written "Chanze," one of the few misspellings in the book. Several sections are occupied with the engineering side of the subject, such as natural and artificial draught, carbolic acid pumps, and methods of filling and emptying kilns.

A section is devoted to the composition and properties of the raw materials and products, and contains a number of tables of analyses of specimens from various localities and the effect of impurities, such as silica, etc. It is pointed out that many limestones contain bitumen and other organic substances which, though combustible, do not diminish the fuel consumption during burning, because they are volatilised during the pre-heating period, and in fact absorb a portion of the energy of the fuel in the process of volatilisation. A section of general interest is one in which various appliances are described for the control of the burning process and testing of the products, etc. One point may be noted, that for observing the flow of gases, the device first mentioned, depending on the insertion of a throttle disc in the gas main, would be less reliable than the Pitot tube mentioned later.

The book is well printed, and the text is illustrated with 270 diagrams and plates which on the whole are clear, but some are on rather too small a scale and some of the graphs are difficult to interpret, as they are plotted vertically, instead of horizontally, on the page. Certainly the book can be recommended to those who are directly connected with lime-burning, and others who are interested in the application of science to industry will find much that is not only of value, but also suggestive to them. A book of this type would form very useful reading for students of chemical technology, as it gives illustrations of the way in which technical problems can be attacked and solved.

The author is an enthusiast on the subject of lime-burning, and the wide range of application of the products in commerce and industry. Two quotations from the book seem to the writer to sum up the author's mental attitude—"Kalk ist die Grundlage jeder Kultur" and "Beobachtung ist alles." Though one might demur in accepting the former dictum, no objection can be raised to the latter.

WALTER C. HANCOCK

DIE CHEMIE DES STEINKOHLENTEERS. By GUSTAV SCHULTZ. Vol. I. *Die Rohmaterialien*, edited by ERWIN FERBER. Pp. viii+568. Fourth edition, completely revised. Brunswick: F. Vieweg u. Sohn A.G., 1926. Price, bound 42.50 r.m.: paper 39.50 r.m.

The last edition of Schultz's work on the "Chemistry of Coal Tar" appeared 27 years ago, so that considerable revision has been necessary in the preparation of the present edition. Judging by the first volume, which is under consideration, and which deals with the raw materials, the revision has been carried out in a thorough manner. The subject is treated particularly in its relation to the artificial organic dyestuffs, which themselves are dealt with in the second volume of the complete work, which has yet to appear. This volume is divided into three principal parts, dealing with the raw materials, intermediates, and notes on technical apparatus respectively. The section on raw materials opens with a short historical sketch of the development of the coal-tar industry, followed by a description of the properties of coal tar and the different distillation processes employed in its preparation. Numerous photographs and diagrams illustrate this part of the work.

The second part, dealing with the intermediates, occupies the greater part of the volume. Usually a book of this nature is at first a disappointment to the reader, inasmuch as his first action is to test it as regards its treatment of his own particular fields, which are usually limited in scope, and in which he is, of necessity, something of a specialist. In the case of the reviewer the work responded to this test as well as might be expected, whilst a careful examination of less familiar ground gave the impression that the whole section will prove of interest and use to all those needing a handy book of reference in this very wide field.

The third part gives a somewhat brief account of certain pieces of technical apparatus. Such a section is rarely of use to those in industry, but it might have been made of greater interest to students who have not the opportunity of a first-hand knowledge of plant. Thus, the apparatus described consists entirely of vessels used for various purposes, which, after all, are merely enlarged editions of similar laboratory plant. A student might well be expected to translate these familiar articles into terms of iron and steel, but who would expect him to conceive in his own imagination a filter-press or a modern centrifuge? J. E. G. HARRIS

PORTLAND CEMENT: ITS COMPOSITION, RAW MATERIALS, MANUFACTURE, TESTING AND ANALYSIS. By RICHARD K. MEADE. Third edition. Pp. xii+707. Easton, Pa.: The Chemical Publishing Co.; London: Williams & Norgate, 1926. Price: \$10.

The earlier editions of this book gained a reputation as a treatise that would appeal to and teach those actually concerned with the production of Portland cement, and the present issue should enhance that reputation. It is written in that spirit of free and open dissemination of information which is characteristic of industrial life in the United States, because so far as cement manufacture in that country, at any rate, is concerned the experience of one factory is usually available for other factories, and

even foreigners are not excluded from the community. We have here the astounding spectacle of a consulting cement expert publishing what one imagines must be a part of his stock-in-trade, if such a term is permissible in this connexion. It is rarely that discussions of some of the subjects here dealt with, such as the repairs costs of different classes of mills, the man-hours requirements of cement production, and the loss of heat by radiation from cement coolers, are to be found in print, and the information that is given has the value of being founded on experience. The raw materials, process of manufacture, and methods of testing of Portland cement are dealt with exhaustively in a scientific fashion, but always with a practical knowledge of the subject.

The thermal efficiency of rotary kilns is of vital interest to cement manufacturers because of its important bearing on cost of production, and this subject is discussed on the basis of heat balance sheets in a chapter on the scientific considerations of the burning process. There are many matters on which cement manufacturers hold various opinions, and the author's presentation of evidence and views on such are interesting and valuable. The effect of clinker-weathering and percentage of lime in the clinker upon the power required for grinding, the power required for running rotary kilns of various sizes, the cost of lubrication in cement works, the cost of building cement works, the absorption and distribution of power in cement manufacture, the design of coal-extraction screws, the capacities of rotary kilns—are all subjects of prime importance in the industry upon which information is always welcomed.

One of the more modern developments of cement manufacture is the application of the waste-heat boiler to recover the heat in the gases leaving the rotary kiln, and the actual results from a number of installations are given, with such useful details as the design of the air-sealing ring needed with the plants.

The cement works chemist is well catered for by detailed descriptions of methods of analysis (including rapid methods for works routine) based on personal experience, coupled with details of automatic sampling devices, the area required for laboratories, laboratory grinding, etc.

Being of American origin, the conditions dealt with are those existing in the U.S.A., and, although this does not materially detract from the utility of the book, lack of intimate knowledge of the British cement industry has led to statements which call for comment. The standard of British cement quality quoted is the obsolete British Standard Specification published in 1910, which has since been revised three times, and this doubtless accounts for the unfounded claim made by the author that American cement is superior to that manufactured in any part of the world. The existing British Standard Specification demands a tensile strength of 325 lb. per square inch at 7 days, and when this is compared with the American standard of 200 lb. per square inch there is no room for doubt as to the respective standards of quality in the two countries. The author's statement that cement ground to pass 90% through a 200-mesh sieve is impracticable could only have been written in ignorance of the fact that thousands of tons of British Portland (rapid hardening) cement are ground to pass 98% through the 200-mesh sieve.

THE MANUFACTURE OF ENAMEL PAINTS. By DOUGLAS WAIT. Pp. viii + 152. London: Scott, Greenwood & Son, 1927. Price 10s. 6d.

The title of this little volume is somewhat misleading. Actually, the book contains a very elementary account of the physical and chemical properties of paint and varnish materials with some special reference to the manufacture of enamel paints. The book may be of great value to students in evening classes who already have some knowledge of the practical side of paint and varnish manufacture, but it is not likely to be of much use to the general technical chemist who wishes to acquire some information on this branch of industry. Technical terms, well understood in the trade, are frequently introduced and taken for granted without any definition or indication of their meaning being given.

Part I comprises two chapters dealing with the elementary chemical and physical properties of pigments and two chapters devoted to white pigments. These are the best in the book, and give a brief but clear and, on the whole, accurate account of the opaque as well as the semi-opaque and transparent white pigments. Part II is concerned with paint and varnish mediums, and includes chapters dealing with thinners, oil bases, driers, etc. The information in this section is somewhat too scanty, and is not always very accurate in giving a good idea of modern methods. Part III is nominally devoted to enamel paints, but only the last two out of four chapters actually deal with the enamel paints themselves. Curiously enough, these chapters are the least satisfactory in the whole book, and are far too brief and scrappy to be of any value.

In spite of the adverse criticisms which it has been necessary to make, the book has many good features, and it might be found very useful as the basis of elementary instruction in the chemistry of paints and varnishes. It is well printed and illustrated, and is written in a clear and lucid style, though the number of split infinitives is somewhat formidable. The price is too high for a small elementary book of this type, and it is to be hoped that a second edition may appear at a price to place it more easily within the reach of elementary students, and others likely to find it useful.

PERCY MAY

LUBRICATION IN COLLIERY PRACTICE. By N. SIMPKIN, M.Sc., Assoc.M.I.Min.E., and A. DAWE, B.Sc. Pp. xiv + 167. London: The Colliery Guardian Co. Ltd., 1926. Price 10s.

Messrs. Simpkin and Dawe have set out to place in the hands of colliery managers, engineers and others engaged in actually running or supervising colliery plant, a small reference book into which one could dip at all and sundry times when desiring to know what grade of oil to purchase for lubrication purposes, and they have certainly achieved their aim.

Not only colliery engineers, but any engineer who is responsible for the proper running of machinery—nay, even the fitter-mechanic who is in charge of a particular machine will benefit (and the machinery also) by having this little book by them.

Really and truly the book consists of Chapter No. VII, but the other chapters are very interesting, and written in very concise form; the absence of padding is particularly pleasing, and the language and terms used are such as not to befog even the veriest mechanic.

Not only are the chapters describing the testing and interpretation of tests written interestingly, but the authors have departed from the usual method of describing the apparatus by borrowing the description from catalogues, and have gone out of their way in plentifully annotating the precautions required in carrying out the tests, which generally prove them to be masters of their job.

Having to deal presumably with the oils on the market or available for uses in collieries, the authors have perhaps made a little too much of compounded oils, and it may be as well perhaps to point out that to use compound oils in steam cylinders in presence of high-temperature and high-pressure superheated steam is like the bicycle lamp on the bicycle, "just sufficient to satisfy the policeman," since under the conditions prevailing, in such a steam cylinder the animal or vegetable oil used for compounding splits up into its chemical components and does not add to the effectiveness of the lubrication; but, on the contrary, results in sticky, semi-charred, gummy substance depositing on the slide valves and rods.

There is no engine oil, of whatever description, used or required to be used by the engineer which cannot be obtained as a pure mineral oil.

N. A. ANFILOGOFF

CASEIN: ITS PREPARATION, CHEMISTRY AND TECHNICAL UTILISATION. By E. L. TAGUE, Ph.D. Pp. v + 218. London: Constable & Co., Ltd., 1926. Price 17s.

The purpose of this book, as stated in the preface, is to explain the chemistry and the industrial uses of casein in the light of present-day practise. The first half is taken up with a study of the chemical and physical properties of casein; much space is occupied in detailing methods of preparation of pure casein and many of its compounds. But the author does well to point out the necessity for a large amount of intensive research work before the constitution and properties of the substances whose methods of preparation are described, are properly understood. The second half is taken up with a consideration of the methods of the technical preparation and of the uses of casein, and includes about thirty pages devoted to patents and prescriptions. The book supplies a much-needed want, and it is a useful addition to the literature of a substance whose remarkable properties endow it with great technical and commercial possibilities. If for no other reason the extensive bibliography should recommend the book to a place in all technical libraries.

R. A. BERRY

PHOTOGRAPHIC CHEMICALS AND CHEMISTRY. By J. SOUTHWORTH and T. L. J. BENTLEY. Pp. vi + 121. London: Sir Isaac Pitman & Sons, Ltd., and Henry Greenwood & Co., Ltd., 1927. Price 3s. 6d.

This book is not intended for the critical reader, and it would be unfair to review it in too critical a spirit. The authors have "hitched their wagon to a star."

when they state in the preface that "the volume is designed to give the reader a fully up-to-date and reasonably accurate account of the known facts and the theories that mark the modern science of photographic processes." If they have not quite achieved all they set out to do, they have produced a very readable little book which should prove useful to many photographers. It may be doubted whether the first part, an introduction to chemistry, is justified in its present form, and whether a single chapter of definitions would not be adequate, leaving more space for essentially photographic material. This would permit of a welcome expansion of the latter part of the work, which deals with negative processes, development, printing-out papers, etc. There is a good list of photographic chemicals, with their properties and uses, and a list of solubilities, concluding with a somewhat inadequate index. There are a number of slips in the text and a few misstatements, which do not, however, detract from the usefulness of the book, which is quite the best of its kind that has been published at so low a price. A word of praise is due to the publishers for the very excellent printing and the freedom from typographical errors. H. W. GREENWOOD

HIGH VACUA. By Dr. G. W. C. KAYE. Pp. xii+175. London: Longmans, Green & Co., Ltd., 1927. Price 10s. 6d. net.

High vacuum technique has, largely under the influence of the electric lamp and discharge tube industry, made unprecedented strides during the past twenty years. The development of the mercury vapour pump by Gaede, Langmuir and others has enormously facilitated the rapid production of low pressures; and side by side with this and other improvements in pump design has grown up a system of vacuum routine, much of which was unknown a decade or so ago.

This routine is dealt with in a very readable and practical manner in the volume under review. Much of the work is necessarily devoted to descriptions and diagrams of pumps, the statements not only of the limit of vacuum obtainable, but also of the relative speed of pumping being particularly welcome, although the actual dimensions of the pumps are seldom given. The efficiency of modern diffusion and condensation pumps would seem to be yet another confirmation of the real existence of molecules and of the kinetic theory, since the principles which govern efficiency of exhaustion in this way are based directly on the kinetics of molecules having abnormally long free paths.

Of general vacuum routine, fused metal-to-glass joints are particularly clearly treated. Many metals, in addition to platinum, are wetted by molten glass; and, even in those cases in which the coefficients of expansion differ considerably from that of glass, permanent joints may be made by suitable construction. This is of special importance in the case of copper, since it allows electrical leads to be fused directly into the glass. Analogous to these are joints between metal and silica, and between silica and glass. Many other practical points, such as the importance of wide connexions in high vacuum apparatus, the action of so-called "getters" for eliminating the last traces of

gas, the construction of mercury traps, the elimination of adsorbed gases, and the quantitative measurement of extremely low pressures are also dealt with.

Above all, Dr. Kaye is to be congratulated on having produced a book in which so much of the atmosphere of actual working conditions is reflected. It is a volume which should be of great practical help in the many branches of chemistry and physics in which high vacua are used. F. B. M.

THE LEAD STORAGE BATTERY. By H. G. BROWN, A.M.I.E.E. Second edition. Pp. 186. London: The Locomotive Publishing Co., 1926. Price 5s.

This work, which is divided into ten chapters with appendix, deals generally with the lead accumulator, and, although obviously written for those in charge of storage battery installations of moderate size, will be found useful by those whose interest in electrical storage does not extend beyond the cells required for wireless equipment or the motor car. The electrical accumulator industry has been transformed and enlarged beyond all expectation by the introduction of wireless and the rapid development of the autocar in this country, and there is a real call for some such publication as the above.

The treatment, which is essentially practical in character, will prove of great value to those for whom it is written. With a sense of fitness which characterises the whole work, the author summarises his advice to battery users in a series of "Don't's," all of which are pertinent, the last being well worth reproduction, viz., "Don't remain in doubt—consult the manufacturer if anything unusual occurs, and shift the responsibility on to him."

The book is copiously illustrated, but, as is often the case in many such works, a large number of the illustrations are so lacking in detail as to be of very little value. The author describes a useful series of chemical colorimetric tests for impurities in battery acid, and provides a novelty in the form of printed colour standards against which comparison should be made. For those in charge of storage batteries, the work can be thoroughly recommended, whilst to those concerned with small units it will prove a useful and interesting source of information, and it is to be hoped that in future editions the author will devote even more space to the treatment of the needs of this very large class of user.

C. A. KLEIN

CANADIAN INDUSTRIAL NOTES

It is announced that the British syndicate interested in the development of the north and east side of the Lake St. John district, Quebec, include Pease Partners & Co., of Darlington.

The Cooper Leaf Tobacco Company will erect a tobacco plant at Wallaceburg, Ont. The company will confine its immediate attention to the drying and curing of tobacco for the British market, but eventually it will manufacture tobacco products.

The Pabst Brewing Co., Saskatoon, Ltd., is erecting a brewery at Saskatoon, Sask., which will cost in the vicinity of \$300,000. The famous Pabst Brewing concern of Milwaukee, U.S.A., is interested in the new plant.

MERCURY FROM COAL TAR

By W. KIRBY, B.Sc.

The company with which the writer has the honour to be associated operates continuous stills, which work on the principle of heating a stream of tar to a temperature such that the tar is sharply divided into two fractions, pitch and oils. The oils pass over as mixed vapours into a series of three condensers maintained at decreasing temperatures, where anthracene oil, creosote oil, and light oils are deposited in the order named.

When these stills are dismantled for overhauling, it is a customary experience to discover in "pockets" in the coil of the light-oil condenser quantities of free mercury. In order to arrive at an estimation, a trap was fitted to the lowest part of this condenser. After the lapse of six months the mercury collected in this manner amounted to one part of mercury from 7 million parts of tar. Weekly estimations were then undertaken, the quantities of mercury recovered being now much larger, averaging one part of mercury from 1.5 million parts of tar. It is highly probable that these estimations err considerably on the low side, as it would be expected that the vapourised mercury in the hot oil vapours leaving the pitch separator would preferentially condense in the anthracene and creosote condensers. It is a curious fact, however, that mercury is never found in these condensers. This may be due to the mercury being colloiddally dispersed in the heavy oils, a phenomenon which would be favoured by its condensation in minute quantities in the presence of enormously larger volumes of oil.

The mercury is deposited in a bright untarnished condition, but if it is not removed for long periods it is then usually discovered associated with variable quantities of mercuric oxide.

The possibility that mercury from this source might have an isotopic constitution differing from that of ordinary mercury induced the writer to send a few pounds of the metal to Prof. Aston, who kindly agreed to undertake its examination. His results, published in *Nature* of April 2, show that no difference in constitution could be detected.

The photographic effects of the mercury were examined in this laboratory, and were found to be normal.

The source of the mercury is possibly cinnabar as an impurity in iron pyrites or dispersed as such in the coal substance, or it may be present in the coal associated with bituminous matter such as idrialite.

The writer is indebted to Dr. C. C. Carpenter for permission to publish this note.

Tar Works,

South Metropolitan Gas Company.

CANADIAN INDUSTRIAL NOTES

The financial statement of the Asbestos Corporation, Ltd., for eleven months ending December 31, 1926, gave operating profits of \$1,237,008, compared with \$781,979 shown by the old company for the entire 1925 period. After the usual interest, depreciation, preferred dividends, etc. were deducted, a balance of \$205,228 was applicable to common stock. The general financial position of the new company is greatly improved over that of the old one.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICE

ANNUAL GENERAL MEETING, JULY 4 to 8, 1927

In accordance with the provisions of By-law 68, notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Debating Hall, The Union, University of Edinburgh, on Tuesday, July 5, 1927, at 10 a.m.

A programme of the Meetings appeared on page 392 of *CHEMISTRY AND INDUSTRY*, for April 29, 1927.

In accordance with the provisions of By-law 23, notice is hereby given that the following members of Council retire from their respective offices at the forthcoming Annual General Meeting:

Mr. Francis H. Carr, C.B.E., *President*; Dr. E. Frankland Armstrong, F.R.S., Professor J. W. Hinchley, Professor J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., *Vice-Presidents*: Mr. W. A. S. Calder, Mr. W. H. Coleman, Dr. William Cullen, and Mr. J. Arthur Reavell, *Ordinary Members*.

Mr. Francis H. Carr, C.B.E., has been nominated for re-election to the office of President under By-law 19, Mr. E. V. Evans, Mr. C. S. Garland, Dr. H. Levinstein, and The Right Hon. Sir Alfred Mond, Bart., M.P., have been nominated Vice-Presidents under By-law 20.

Dr. E. W. Smith has been elected Hon. Treasurer, and Dr. E. Frankland Armstrong has been elected Hon. Foreign Secretary.

Members are requested to nominate on or before May 13 next, fit and proper persons to fill the four vacancies among the Ordinary Members of Council. Forms for this purpose can be obtained from the General Secretary of the Society.

By-law 22. An ordinary Member of Council shall be nominated by five or more members upon Form B in the Schedule, a copy of which form shall be furnished by the General Secretary upon the written or verbal request of any member; but a member shall not be eligible to sign more than one such nomination form, and the member nominated shall sign the declaration set forth on the form.

A nomination shall be declared invalid by the Council if:—

(a) The member thereon nominated is disqualified for election, or ineligible to be elected, as provided by the By-laws.

(b) The nomination is not made on the authorised printed form, or substantially not in the manner directed thereon.

(c) The nomination form is signed by less than five members not disqualified or not ineligible to nominate as provided by the By-laws.

(d) The nomination form is not received before or upon the day appointed therefor.

(e) The member nominated has not signed the declaration printed upon the form.

A member whose nomination aforesaid is declared to be invalid shall receive notice thereof from the General Secretary, and shall not be submitted for election.

J. P. LONGSTAFF,
General Secretary

CHEMICAL ENGINEERING GROUP

An additional meeting of the Chemical Engineering Group was held in the Cinema of the American Film Company at Wardour Street on Monday evening, April 25, under the chairmanship of Mr. F. H. Rogers, when Professor J. W. Hinchley gave a paper on the Holley permanent mould machines.

At the beginning of the lecture Professor Hinchley dealt with the great utility of such a machine in repetition work, and touched upon the difficulties that are to be encountered when permanent moulds have to be used for iron castings. The moulds in this machine are formed of two light hollow cast-iron moulds, which can be opened and closed by means of a toggle joint mechanism. The thickness and outer surfaces of these moulds are designed to ensure a proper rate of removal of heat after the metal has been poured, whilst the inner surface is coated with a refractory material. This material must be sufficiently hard to resist the cutting action of the molten metal, and of sufficient thickness to transmit the heat at the proper safe rate, and of such a nature that no gases are formed when in contact with the molten metal. The machine in its latest form consists of a horizontal circular table, which is rotated at the rate of one revolution every two minutes. On this table or merry-go-round are fixed twelve of these moulds. After a casting has been discharged from a mould the mould is cleaned by a blast of air at a pressure of about 200 lb. per sq. in., and is then coated with a layer of carbon about $\frac{1}{32}$ in. thick from an acetylene flame. Should a core be necessary, it is then put in position by hand, and the mould closed. Further rotation of the table brings the mould opposite the pourer, when it is filled with molten metal. After filling, the table rotates through a distance which allows sufficient time to elapse for the molten metal to set, and when this point is reached the mould is automatically opened and the casting ejected by suitably placed ejection pins. Further rotation of the table brings the mould round to the air blast where the cycle of operations is repeated. On such a machine casting carburettor parts, motor-car pistons, etc., a man can pour four hundred castings per hour.

Professor Hinchley also discussed the composition of the iron used in such repetition work, as well as the strengths of the castings produced. He also drew attention to the fact that an extremely uniform casting was obtained, and therefore the allowance for machining could be considerably reduced from that prevalent in repetition work. A number of castings were on view to illustrate the various points discussed.

After the lecture a film was shown of the works of the Holley Carburettor Company, in which both the large single-mould machines and those of the rotary type were shown under working conditions. The film was followed by an interesting and pertinent discussion, in which a large number of gentlemen took part.

BIRMINGHAM AND MIDLAND SECTION

At the meeting held at the University of Birmingham on April 5, Mr. Collis presiding, Mr. A. A. King, works manager, Messrs. Albright & Wilson, Oldbury, read a paper on "Ultra-violet light."

One of the most urgent needs of chemists and others was, he said, practical filters by means of which one might isolate any selected region in the ultra-violet spectrum. None is at present available, and we are driven to compare differences in reaction obtained with filters which still allow visible as well as more or less ultra-violet rays to pass through them. Perhaps the most useful filter for fluorescence work is Chance Bros.' ultra-violet glass, which cuts out all but the extreme red of the visible spectrum, and transmits rays from 4000Å to 3250Å.

It is physiologically impossible to experience complete darkness in a room into which invisible ultra-violet rays are emitted. Even though every other material within range is non-fluorescent, the lens of the eye is fluorescent in these rays, and the retina becomes aware of a blue, misty illumination. This principle was made use of during the war for invisible light signalling.

A much more important application of this effect is that, by their fluorescence, certain imitation gems can be distinguished from the natural stones. The method is not confined to such materials, and it promises important development. The presence of minute impurity in some substances can be detected by its fluorescence, and afterwards identified by chemical methods.

Even laboratory "distilled" water may profitably be examined in the rays. Certain impurities, otherwise unsuspected, show up, and the author demonstrated the need for a succession of redistillations, culminating in double distillation in platinum vessels, to obtain a practically non-fluorescent sample of distilled water. Ultra-violet light could be used for testing the presence of arsenic. Some twelve months ago he had recourse to the most refined of the known methods of detecting and estimating minute quantities of arsenic in food substances. Finally he selected the Gutzeit method, which gives a mercury-arsenic yellow stain, as most suitable for further examination. An attempt to intensify the stain in monochromatic light served its purpose, but it occurred to him to expose the stains to ultra-violet radiation. It was discovered that by the method one may estimate quantitatively arsenious oxide of an order of minuteness beyond what has been hitherto possible with any other method with which he was acquainted. Absorption of the rays by the mercury arsenic stain makes this intensely black, so much so that stains which are quite indistinguishable in ordinary light stand out a startling black upon a fluorescent background. They had been able to estimate with certainty as little as 0.00000005 gram as As_2O_3 , and to detect even smaller masses.

Arising from this work the author showed that, with good samples of crystallised mercuric chloride fluorescing in the rays, some parts are a bright pink, while others are very faintly blue. This mercuric chloride twice recrystallised in the laboratory showed no sign of the pink fluorescence, which was found to be due to the presence of mercurous chloride. The light showed the distinction between vegetable and mineral oils; amber (genuine and artificial); uranium acetate and nitrate; and some organic and inorganic pigments. Such experiments opened up a new field of titration work. It was suggested by work done by Mellet and Bischoff in

detecting obliterated and forged signatures on cheques etc. by exposing them to ultra-violet radiation. His example was the titration of phosphates which he had found useful for muddy liquors. To an ordinary sodium phosphate in neutral solution was added a drop of saturated solution of quinine sulphate. As long as the solution is alkaline there is but a trifling fluorescence, but the approach to acidity is heralded by an intensely blue fluorescence. This is due to the temporary and eventually permanent formation of the acid sulphate of quinine. He suggested that the method may lend itself to the investigation of the mixing of reactive and other solutions.

CALENDAR OF FORTHCOMING EVENTS

- May 6. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual General Meeting. Imperial College of Science and Technology, Kensington, S.W.7. Formal business meeting at 6 p.m. An informal dinner will be held at 6.30 p.m., and at 8 p.m. a paper entitled "Chemical fire extinguishers" will be read by Dr. W. R. Ormandy.
- May 6. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, 16, St. Mary's Parsonage, Manchester, at 7 p.m. Joint meeting with the Fellows of the Chemical Society resident in Manchester and district. "Mechanism of some simple reactions from the standpoint of the electronic theory of valency," by Prof. R. Robinson.
- May 7. BIOCHEMICAL SOCIETY, The University, Oxford Road, Manchester, at 3 p.m. (1) "Variations in the serum calcium of rabbits," by Kathleen Cullane and S. W. F. Underhill. (2) "Attempted isolation of a type precipitinogen from *B. aertrycke* Mutton," by F. C. Happold. (3) "Experiments on the origin of succinic acid in muscle and liver," by P. W. Clutterbuck. (4) "Action of tyrosinase on phenols," by C. E. M. Pugh and H. S. Raper. (5) "Chemical changes in muscle," by E. Boyland and A. D. Ritchie (introduced by H. S. Raper). (6) "The carbohydrate-phosphate component of animal nucleic acid," by J. Pyde and J. M. Peterson. (7) "Some observations on methylated glycerophosphates," by J. Pyde and E. T. Waters. (8) "Fermentation of propionic acid by *Aspergillus niger*," by T. K. Walker and P. D. Coppock (introduced by H. S. Raper). (9) "Hemocyanin. Part IV. The dependence of the shape of the oxygen dissociation curve on the state of ionisation of the protein," by Ellen Stedman and E. Stedman.
- May 11. INSTITUTE OF METALS, Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, at 8 p.m. Seventeenth Annual May Lecture on "The growth of crystals in supersaturated liquids," by Sir H. A. Miers.
- May 11. ROYAL SOCIETY, Burlington House, Piccadilly, W.1, at 8.30 p.m. *Conversazione*.
- May 12. OIL AND COLOUR CHEMISTS' ASSOCIATION. Annual General Meeting. Rooms of the National Federation of Paint Manufacturers, 8, St. Martin's Place, Trafalgar Square, London, W.C.2, at 8 p.m. "Some physical factors influencing properties of paint pigments," by A. de Waele.
- May 18. CHEMICAL SOCIETY, Theatre of the Royal Institution, 21, Albemarle Street, W., at 5.30 p.m. The Faraday Lecture entitled, "Problems and methods in enzyme research," by Prof. Richard Willstätter.

THE INSTITUTE OF FUEL

A joint meeting of the Vice-Presidents and Members of the Councils of the Institution of Fuel Technology and the Institution of Fuel Economy Engineers was held under the chairmanship of Sir Alfred Mond at 37, Lowndes Square, S.W.1, at 3 p.m. on April 29. As President of both Institutions, in November last Sir Alfred Mond, having found a general desire both amongst those most closely associated with the problems of fuel economy and amongst those throughout the country who have a general interest in the question, that the two existing Institutions should be merged into one, suggested terms of fusion.

The following terms of fusion were subsequently accepted by the Councils of both Institutions:—

(1) That the name of the merged Institutions be "The Institute of Fuel."

(2) That the Councils of both Institutions as constituted at present be merged and form the Council of the "The Institute of Fuel," and that in the autumn following the inauguration of the Institute of Fuel a new Council shall be elected by ballot of the members of the Institute.

(3) That the present Honorary Secretaries of each present Institution be joint Honorary Secretaries of "The Institute of Fuel."

At the meeting the final steps for the fusion of the existing Institutions and the inauguration of the "Institute of Fuel" were taken. Sir Alfred Mond expressed his great gratification that the fusion had been successfully accomplished, and thanked the Vice-President, Chairman, and Members of the Council of both Institutions for their co-operation in bringing about the present happy result. The essential importance of the problems connected with fuel economy and fuel technology to the future of British industry was becoming increasingly recognised. The Government was vitally interested in the subject, and had appointed a National Fuel and Power Committee, of which he had the honour to be chairman, to investigate and consult upon the various problems in their many aspects. That Committee was progressing satisfactorily with its work, and it was of the utmost importance that there should be a unified Institution, important in numbers and personnel, to investigate, advise and instruct the Committee and the community on these highly technical matters. From the readiness to co-operate which had already been shown, he felt that the "Institute of Fuel" was being inaugurated under the most favourable auspices. There have been many who had been waiting to join a unified Institute and now doubtless they will all come forward to add strength and numbers to an institution which is to play a great part in the future of British industrial expansion.

Sir Alfred Mond moved the formal resolutions to give effect to the fusion, which were seconded by Sir Hugh Hirst, who said that on account of the national importance of the subject and of the fact that it was essential there should be one body to deal authoritatively with the problems of fuel technology, he was very glad that the fusion had been effected.

Sir William Larke proposed, and Sir Philip Dawson seconded, the appointments of Mr. H. L. Pirie and Mr.

Edgar C. Evans as joint Honorary Secretaries of the Institute of Fuel. This was carried unanimously.

The following were present at the meeting:—Sir Alfred Mond (President), Sir Hugo Hirst, Sir David Milne-Watson, Colonel Sir William Smith, Prof. H. B. Dixon, Prof. R. V. Wheeler, Sir William Larke (Chairman, Institution of Fuel Technology), Mr. P. C. Pope (Chairman, Institution of Fuel Economy Engineers), Messrs. G. R. Thursfield, F. A. Freeth, T. Barratt, A. W. A. Chivers, R. Lessing, John D. Troup, Sir Philip Dawson, Messrs. H. Tomlinson-Lee, John Bruce, J. Gander, T. Trimmell, W. M. Selvey, Edgar C. Evans, S. McEwen, W. A. Woodeson, E. W. L. Nicol, H. L. Prie, L. C. Harvey, N. W. Travers, and T. Hardie.

CERAMIC SOCIETY

The annual meeting was held at the North Staffordshire Technical College, Stoke, on April 11, Mr. F. Turner presiding. Mr. Frank West, President of the Refractory Materials Section, was present. The Council, in their 28th annual report, stated that there was a membership of 707 and 77 collective members. During the closing sessions eight meetings were held at Stoke, and the Refractory Materials Section had a successful two days' meeting at Leeds in September. The arrangements had been completed for the visit of members to Czechoslovakia. Between 70 and 80 members were intending to go. They would be the guests of the Czechoslovakian Ceramic Society. The President announced that the President for the ensuing year would be elected by the Refractory Materials Section. The following other officers were elected: Vice-Presidents, Mr. George Price, Mr. B. J. Moore, and Mr. Walter Emery; Members of Council, Messrs. A. J. Campbell, C. D. Grimwade, G. Price, T. G. Simpson, G. Campbell, J. A. Audley, A. Heath, G. Allman, J. H. Colclough, T. A. Simpson, T. Simpson, D. F. W. Bishop; Hon. Sec., Dr. J. M. Mellor.

CORRESPONDENCE

THE LIFE OF FABRICS

SIR:—The Department of Scientific and Industrial Research has just issued a pamphlet on "Co-operative Industrial Research" which has received a very good Press. This is most welcome to those people who know what struggles some of the associations are having to maintain existence when some of the trades with which they are connected are in such bad financial condition. It seems a pity that such a ludicrous estimate should be included as that which is given on the question of laundry research. I refer to the item, "Depreciation of fabrics calculated on five years' life." I don't think I am wrong in assuming that collars and sheets form staple articles in a laundry's operations. Is anybody—scientific or otherwise—expected to believe that collars and sheets last five years when sent to laundries. The Laundry Research Association has no need to be bolstered up by such a ludicrous estimate. If the Laundry Research Association would educate laundries to cease using perborates and hypochlorites, the length of life of collars etc. would be increased, though not to a period of five years.

* Yours faithfully,
C. M. WHITTAKER

PERSONAL AND OTHER ITEMS

The King has been pleased to nominate Dr. H. H. Dale, F.R.S., to be, for five years, a member of the General Council of Medical Education and Registration in the United Kingdom, in succession to Sir Nestor Tirard, M.D.

The Rt. Hon. Sir Alfred Moritz Mond, M.P., has been appointed a Director of the Westminster Bank.

Mr. E. M. Myers has been appointed manager of the coke-ovens and by-product plants of Bolekow, Vaughan & Co. in the Bishop Auckland district.

The University of St. Andrews will confer the honorary degree of LL.D. on Sir Alfred Mond, P.C., M.P., and on Sir Richard Gregory, the Editor of *Nature*, at the graduation ceremonial on June 28.

Prof. C. A. Edwards, D.Sc., professor of metallurgy at the University College of Swansea, has been appointed Principal of the College.

The Council of Manchester University has accepted the resignation of Professor F. L. Pyman, D.Sc., Ph.D., F.R.S., who has been appointed head of the research department of Messrs. Boots, Ltd., Nottingham. Prof. Pyman has held the Chair of Technological Chemistry in the Faculty of Technology since 1918.

Dr. G. J. Robertson, M.A., B.Sc., has been appointed to the senior lectureship in chemistry at St. Andrews, vacant through the resignation of Dr. G. McOwan.

At a recent meeting of the Académie des Sciences, it was announced that Baron Edmond de Rothschild had made a gift of 38,000,000 f. (about £306,000) for the formation of an institute for chemical and physical research as applied to biology.

April 30, 1927, marked the completion of the first century of University College, London, which has always been a centre of research as well as of teaching. A chemical laboratory was opened in the college as early as 1828, and the staff has included distinguished investigators such as Thomas Graham (of colloid fame), A. W. Williamson, and Sir William Ramsay.

We deeply regret to learn of the death of Professor Starling, the eminent physiologist, to whom we owe the discovery of hormones, and much fundamental work on the physiology of the blood system.

The late Mr. A. W. Scott, for 55 years professor of science at St. David's College, Lampeter, left £33,521. Amongst other bequests he left £7000 to the University of Cambridge, and £1000 to the Royal Society for the advancement of physical science, £250 to the British Association, the Physical Society and the Institute of Physics; and an interest in the residue to the Universities of Oxford and Cambridge.

The late Mr. W. H. Stuart, J.P., chairman of the British Flint Glass Manufacturers' Association, left £44,463.

Research Association of British Paint, Colour and Varnish Manufacturers

The Director of Research to this Association, Dr. L. A. Jordan, has issued some notes on the activities of the Association, from which we learn that the subscriptions already guaranteed exceed the minimum required to secure the full participation of the Department of

Scientific and Industrial Research for the five years. A programme of research has been drawn up, and steps are being taken to inquire into the problem of growing certain oil seeds, particularly tung and perilla, within the Empire. Co-operation with the British Electrical and Allied Industries Research Association on problems of insulating varnishes is contemplated, whilst the Boot Trade Research Association has pointed out that the cracking of patent leather is essentially a paint problem. Further co-operation has begun in connexion with paint and varnish standard specifications, colour standards, and the measurement of colour fading, and exposure tests. The Laboratory at Teddington is practically ready for occupation, and good progress has been made in the formation of a card index and the compilation of records of work in particular subjects.

British Association

The ninety-seventh annual meeting of the British Association will be held at Leeds on Wednesday, August 31, to September 7, 1927. The president is Prof. Sir Arthur Keith, M.D., LL.D., F.R.S., and the sectional presidents include Prof. E. T. Whittaker, F.R.S. (Mathematical and Physical Sciences), Dr. N. V. Sidgwick (Chemistry), and Mr. C. G. T. Morison (Agriculture).

High-Pressure Gas Research

The Department of Chemical Technology of the Imperial College announces that a special course of eight lectures on "High-pressure gas research" will be given on Fridays at 4 p.m., commencing May 6, by Prof. W. A. Bone, D.Sc., F.R.S., and Drs. D. M. Newitt and D. T. A. Townend. The fee for the course is one guinea.

Lectures in Metallurgy

The Worshipful Company of Armourers and Brasiers announces that a course of three lectures on "Special steels and their application in engineering," will be given at the Sir John Cass Technical Institute, 31, Jewry Street, Aldgate, E.C., by Dr. W. H. Hatfield, on May 17 and 31, and June 14, at 6.30 p.m.

The Armourers and Brasiers' Company also announces that a course of three lectures on "Oxidation, corrosion and passivity of metals," will be given at the Royal School of Mines, Prince Consort Road, South Kensington, S.W., by Mr. U. R. Evans, on May 18 and 25, and June 1, 1927, at 5.30 p.m. Admission to both courses is free without ticket.

The Company has also founded senior and junior industrial bursaries, particulars of which may be obtained on application to the company's offices at Armourers' Hall, 81, Coleman Street, London, E.C.2.

Research Scholarships in Technology

The Governing Body of the Manchester College of Technology announces that a limited number of Research Scholarships in Technology (each of a value not exceeding £100) will be awarded in July. Applications must be received before July 6. Subjects in applied chemistry and other technological subjects can be chosen for the research, which will be carried out in the College (Faculty of Technology of the University of Manchester).

Ramsay Memorial Fellowships

The Ramsay Memorial Trustees at the end of June will consider applications for a Ramsay Memorial Fellowship for Chemical Research. The value of the Fellowship will be £250 a year, to which may be added a grant for expenses not exceeding £50 a year. Applications must be not later than June 6. Full particulars as to the conditions of the award are obtainable from the secretary, Ramsay Memorial Fellowships Trust, University College, Gower Street, London.

The German Dye Trust

The *Times* reports that at a meeting on April 28 of the board of the I.-G. Farbenindustrie, it was stated that the gross profit for 1926 was 168,074,000 Reichsmarks, and the net profit, after writing off 75,236,860 Reichsmarks, was 68,718,255 Reichsmarks. A dividend of 10% is proposed. The board expressed its approval of the results shown during the year 1926. The improvement in industrial conditions had been evidenced in a marked degree in the business of the I.-G. In spite of increased competition, it had been possible to increase production and exports. The market in Germany for pharmaceutical products had left something to be desired, but exports had developed favourably. It was noticeable, however, that several countries had adopted a protectionist policy for the encouragement of pharmaceutical industries at home. Owing to the fusion with the Cologne-Rottweil A.G., the activities of the I.-G. in the artificial silk domain had increased. In return for corresponding concessions, the I.-G. will factories immediately. It was prophesied that the I.-G. would shortly be taking a prominent part in German benzene production, and a large annexe to the present Merseburg works had been erected for the purpose of carrying out coal hydrogenation on an industrial basis.

Glanzstoff Silk in America

The Vereinigte Glanzstoff Works, of Elberfeld, has established the American Glanzstoff Corporation at Wilmington, in America, with a capital of \$7,000,000 7% preference shares and 300,000 shares without nominal value. The new firm will have all the Glanzstoff patents at its disposal, and will produce especially fine artificial silk thread. The average daily production at the commencement will be about 7 tons.

COMPANY NEWS

BRITISH DRUG HOUSES, LTD.

The report for 1926 shows a trading profit of £16,863, compared with £55,300 for 1925. With £6719 brought forward, there is available £12,491. The preference dividend absorbed £9680, leaving £2811, which it is proposed to carry forward. Many adverse factors combined to depress the profits. Being primarily a producing concern, the company suffered heavily from the general strike and the prolonged coal dispute. Also their trade declined with South America, owing to unfavourable conditions in that country. An encouraging increase in the turnover, both in the home and export trade, is recorded during the first three months of 1927.

RUBBER GROWERS' ASSOCIATION

Presiding at the ordinary general meeting on April 28, Mr. E. B. Skinner (chairman) said they deplored the deaths of seven members, including the Hon. C. H. Strutt, who had been a member of the council since 1913. The membership of the association continued to expand. The issued capital represented by the association had now reached £106,000,000. With regard to the accounts, the amount carried forward last year was larger than usual, mainly due to the closing down of the research station in Malaya at the end of October, consequent on the taking over of the Association's scientific staff by the Rubber Research Institute of Malaya, which is now operating in matters of rubber research for the whole of Malaya. The Honorary Gold Medal of the association had been awarded to Sir Edward Rosling and Mr. Eric Miller respectively for services rendered in connexion with the organisation and development of scientific research work for the plantation rubber industry. The work of the propaganda committee had continued in the direction of extending the existing uses of rubber and of investigating new uses. The two principal points of interest during the past year have been the establishment of the American rubber pool and the policy which many producers adopted of holding surplus stocks themselves instead of selling during a time when there was more rubber being produced than was required for the time being. These two factors helped to prevent wild fluctuations in price during 1926. It was believed that the average price for the current year would be 1s. 9d. The chairman felt they could look forward with confidence to the future, as all countries were realising the enormous value of rubber for so many purposes. He had great hopes that rubber would soon be used on a large scale for other purposes than tyres and tubes, which, at present, absorb approximately 80% of the world's output of rubber. With regard to the criticism contained in letters to the Press against the Stevenson scheme, the Association had consistently supported the scheme, and quite recently leaders of the producing section of the industry had publicly expressed their entire sympathy with a continuance of the scheme and pointed out its beneficial effects on the industry generally. The rubber industry lost a great friend and staunch supporter by the death of Lord Stevenson, and members of the Association, in appreciation of his valuable help, had subscribed £2870 to a scholarship fund to be named after him.

AMERICAN CYANAMID CO.

Dividends have been declared of $1\frac{1}{2}\%$ on the preferred stock, and 1% plus $\frac{1}{2}\%$ extra on the common stock.

THARSIS SULPHUR AND COPPER CO., LTD.

A dividend has been recommended of $7\frac{1}{2}\%$, equal to 3s. per share, less tax. After writing off £14,581, the sum of £99,522 has been carried forward. No dividend was declared for 1925.

EASTMAN KODAK COMPANY

The net profit for 1926 amounted to \$19,860,634, after providing for depreciation, Federal taxes, etc., compared with \$18,467,113 for 1925.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
Acid Hydrochloric—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali—£6 15s. per ton, f.o.r. Special terms for contracts.
Bisulphite of Lime—£7 10s. per ton, packages extra.
Bleaching Powder—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4 ton lots.
Borax, Commercial—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride, Solid—£5—£5 5s. per ton, carr. paid.
Copper Sulphate—£25—£25 10s. per ton.
Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
Nickel Sulphate—£38 per ton d/d.
Nickel Ammon. Sulphate—£38 per ton d/d.
Potash, Caustic—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
Sal ammoniac—£45—£50 per ton. Chloride of ammonia £37—£45 per ton, carr. paid.
Salt Cake—£3 15s.—£4 per ton d/d. bulk.
Soda, Caustic, solid—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
Soda Crystals—£5—£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98%—£21 per ton. Sod. Bicarbonate (refined)—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate.—2½d. per lb.
Sod. Phosphate—£14 per ton, f.o.r. London, casks free.
Sod. Sulphate (Glauber's Salt)—£3 12s. 6d. per ton.
Sod. Sulphide conc. solid 60/65—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide—Golden.—6½d.—1s. 5½d. per lb., according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow—1s. 9d. per lb.
Barytes—£3 10s.—£6 15s. per ton, according to quality.
Cadmium Sulphide—2s. 6d.—2s. 9d. per lb.
Carbon Bisulphide—£20—£25 per ton, according to quantity.
Carbon Black—5½d. per lb., ex wharf.
Carbon Tetrachloride—£45—£50 per ton, according to quantity, drums extra.
Chromium Oxide, Green—1s. 1d. per lb.
Diphenylguanidine—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron".—£13 12s. 6d. per ton, f.o.r. London.

Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.

Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbanilide.—2s. 1d.—2s. 3d. per lb., according to quantity.

Vermilion, pale or deep.—6s.—6s. 3d. per lb.

Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.

Charcoal.—£6 15s.—£10 per ton, according to grade and locality.

Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.

Red Liquor.—9d.—1s. 16° Tw. per gal.

Wood Creosote.—1s. 9d. per gal., unrefined.

Wood Naphtha.—Miscible, 4s.—4s. 3d. per gal., 60% O.P. Solvent, 4s. 3d. per gal., 40% O.P.

Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.

Brown Sugar of Lead.—£40 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8½d.—9d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.

Acid Cresylic, 90/100.—2s. 8d.—2s. 9d. per gal. Steady. 97/99.—2s. 1½d.—2s. 6d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.

Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.

Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 8d.—2s. 3d. per gal., ex works in tank wagons.

Toluole.—90%, 1s. 9d. to 2s. 0½d. per gal. Pure, 1s. 10d.—2s. per gal.

Xylol.—2s.—2s. 6d. per gal. Pure, 3s. per gal.

Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.

Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 6d.—1s. 11d. per gal. Solvent 95/160, 1s. 6d.—1s. 7d. per gal. Solvent 90/190.—1s. 1½d.—1s. 4d. per gal.

Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.

Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.

Pitch, medium soft.—7s.—80s. per ton, f.o.b. according to district. Nominal.

Pyridine.—90/140.—8s. 6d.—13s. per gal. Nominal. 90/180.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acid Gamma.—4s. 9d. per lb.

Acid Amidonaphthol disulpho (1.8.2.4).—10s. 9d. per lb.

Acid H.—3s. 3d. per lb. 100% basis d/d.

Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.

Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.

Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.

Aniline Salts.—7d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.

Benzaldehyde.—2s. 3d. per lb.

Benzidine Base.—3s. 3d. per lb. 100% basis d/d.

Benzoic Acid.—1s. 8½d. per lb.

o-Cresol 20/31° C.—4d. per lb.

m-Cresol 98/100%.—2s. 8½d. per lb.

p-Cresol 32/34° C.—2s. 8½d. per lb.

Dichloraniline.—2s. 3d. per lb.

Dimethylaniline.—2s. per lb. d/d. Drums extra.

Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.

Dinitrochlorobenzene.—£84 per ton d/d.

Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.

Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.

Diphenylamine.—2s. 10d. per lb. d/d.

α-Naphthol.—2s. per lb. d/d.

β-Naphthol.—11d.—1s. per lb. d/d.

α-Naphthylamine.—1s. 3d. per lb. d/d.

β-Naphthylamine.—3s. per lb. d/d.

p-Nitraniline.—1s. 9d. per lb. d/d.

m-Nitraniline.—3s. per lb. d/d.

o-Nitraniline.—5s. 9d. per lb.

Nitrobenzene.—6d. per lb., naked at works.

Nitronaphthalene.—1s. 3d. per lb. d/d.

R. Salt.—2s. 2d. per lb. 100% basis d/d.

Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.

o-Toluidine.—8d. per lb., naked at works.

p-Toluidine.—2s. 2d. per lb. ex works, naked.

m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.

Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb. Firm and brk.

Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s. 3d. per oz.; 500 oz. lots—1s. per oz.

Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.

Acid, Camphoric.—19s.—21s. per lb.

Acid, Citric.—1s. 5½d.—1s. 6½d. per lb. Less 5%. Firm.

Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.

Acid, Pyrogalllic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.

Acid, Salicylic.—B.P. 1s. 4d.—1s. 5d. per lb. Technical 11½d.—1s. per lb. Both in good demand.

Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.

Acid, Tartaric.—1s. 2½d. per lb. Less 5%. Firm market.

Amidol.—9s. per lb. d/d.

Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.

Amidopyrin.—8s. 6d. per lb.

Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.

Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.

Atropine Sulphate.—11s. per oz. for English make.

Barbitone.—6s. 6d. per lb.

Benzonaphthol.—3s. 3d. per lb.

Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth

Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—

8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—

8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb.

Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Sub

chloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—

7s. 9d.—8s. per lb. Extra and reduced prices for

smaller and larger quantities respectively; Liquor

Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.

—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—3s. 2d.—2s. 4d. per lb. Potassium.—1s. 9½d.—2s. per lb. Sodium.—2s. 0½d.—2s. 2d. per lb. All spot.

Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 6d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Creosote Carbonate.—6s. per lb.

Ether meth.—1s. 1d.—1s. 11½d. per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiacol Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb., for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron. Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—22s. per cwt., 112 lb. lots.

Magnesium Carbonate.—Light Commercial £33 per ton net.

Magnesium Oxide.—Light Commercial £67 10s. per ton, less 2½%; Heavy Commercial £22 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 11s.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb.

Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonol.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4½d. per lb.

Phenacetin.—3s. per lb.

Phenazene.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar) 97s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 5d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Rosorcin.—4s. per lb. spot.

Saccharin.—55s. per lb. Very limited enquiry.

Solol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 2d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonol.—7s. 6d. per lb.

Tartar Emetio B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.

Thymol, Puriss.—11s.—12s. 6d. per lb., according to quantity. Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (ex Anethole).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. 6d. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 3d. per lb.

Ethyl Cinnamate.—10s. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. 6d. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol (ex Bois de Rose) 15s. per lb.—(ex Shui Oil) 10s. 6d. per lb. Linalyl Acetate.—(ex Bois de Rose) 18s. per lb.—(ex Shui Oil) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—27s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpineol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—13s. per lb.

Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure.—6s. per lb.

Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—9s. 6d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 17s. 6d. per lb. Japanese, 8s. 3d. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than June 25th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C.2, on May 12th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

1.—Applications

Bridgford, Marle, and Gibbons Bros. Muffle furnaces. 10,087. Apr. 21.

Cooper, Henshaw, and Holmes & Co. Treatment of gaseous mixtures. 10,512. Apr. 19.

Davis. Compounds etc. for removal of fur etc. from boilers etc. 10,857. Apr. 22.

Kohout. Furnaces. 10,625. Apr. 20.

Lister et Cie., and Lister. Grinding mills. 10,822. Apr. 22.

Lodge-Cottrell, Ltd., and Lodge. 10,941. See XI.

Pickard. Splitting emulsions. 10,808. Apr. 22.

Semet-Solvay Co. Heat transfer structures. 10,486. Apr. 19. (U.S., 13.5.26.)

Singer. Apparatus for distilling liquids. 10,497. Apr. 19. (Ger., 19.8.26.)

Techno-Chemical Laboratories, Ltd., Gram, and Soderlund. Drying. 10,942. Apr. 23.

Trocknungs- Verschwelungs- und Vergasungs-Ges., and Honigmann. Means for continuous drying of fine granular masses. 10,831. Apr. 22.

Umpleby. Furnaces etc. 10,432. Apr. 19.

Urban Corporation. Separation of gases from mixtures. 10,920 -1. Apr. 23. (Fr., 27.4.26 and 1.5.26.)

I.—Complete Specifications

*8915 (1926). Wood. Pulverising. (269,319.)

15,372 (1926). Minter. Kilns. (269,361.)

17,851 (1926). British Thomson-Houston Co., Ltd. Furnaces. (255,479.)

21,929 (1926). Pedersen. Furnaces. (269,397.)

22,286 (1926). Carborundum Co., Ltd. Driers. (269,956.)

32,793 (1926). Pasquiers. Drying. (263,838.)

*15,434 (1926). Darco Sales Corporation. Reactivating purifying-agents. (269,469.)

*29,999 (1926). Dwight and Lloyd Metallurgical Co. Treating materials. (269,480.)

*5865 (1927). Meyerhofer. Conversion of solids, solutions, and gases. (269,491.)

*9017 (1927). Semet-Solvay Co. Distillation systems. (269,517.)

*10,343 (1927). Polanyi and Bogdandy. Producing finely-distributed mixtures of mutually insoluble bodies. (269,586.)

II.—Applications

Abbott. Compound for testing oil. 10,556. Apr. 20.

I.-G. Farbenind. Manufacture of products from coal etc. 10,480. Apr. 19. (Ger., 16.4.26.) Production of fuel gas. 10,481. Apr. 19. (Ger., 19.4.26.)

Johnson (I.-G. Farbenind.). Production of hydrocarbons of low boiling point. 10,735. Apr. 21.

Pickard. 10,808. See I.

Siemens & Halske A.-G. Means for testing gases of combustion. 10,849. Apr. 22. (Ger., 26.5.26.)

Soc. des Prod. Chim. de Clamecy. Distillation of wood. 10,865. Apr. 22. (Fr., 22.4.26.)

Spindler. Apparatus for production of artificial petroleum. 10,472. Apr. 19.

Tormin. Apparatus for carbonising coal etc. 10,475. Apr. 19. (Ger., 30.4.26.) Manufacture of coke. 10,476. Apr. 19. (Ger., 8.9.26.)

II.—Complete Specifications

30,606 (1925). Meyer. Fuels for internal-combustion engines etc. (269,222.)

446 (1926). Nielsen and Laing. Manufacture of water-gas. (269,234.)

902 (1926). Cox and McDermott. See III.

2636 (1926). Umpleby. Gas-generating apparatus. (269,269.)

*29,603 (1926). Soc. de Recherches et D'Exploit. Pétrolières. Activating carbon or carbonaceous substances and production of combustible gases. (269,477.)

*29,762 (1926). Lundin. Production of carbolic acid gas. (269,478.)

*6818 (1927). Seelig. Cracking of oils. (269,499.)

*9196 (1927). I.-G. Farbenind. Production of liquid hydrocarbons. (269,521.)

*10,040 (1927). I.-G. Farbenind. Manufacture of unsaturated gaseous hydrocarbons and hydrogen. (269,517.)

*10,480 (1927). I.-G. Farbenind. See III.

*10,481 (1927). I.-G. Farbenind. Manufacture of fuel gas. (269,594.)

III.—Complete Specifications

902 (1926). Cox and McDermott. Purification of benzol, petrol, and the like. (269,242.)

*10,480 (1927). I.-G. Farbenind. Manufacture of products from coal tars, mineral oils, etc. (269,593.)

IV. Applications

Brightman, Chorley, and British Dyestuffs Corp., Ltd. Azo dyestuffs. 10,858-9. Apr. 22.

Carmichael (I.-G. Farbenind.). Increasing fastness to light of dyestuffs. 10,861. Apr. 22.

I.-G. Farbenind. Manufacture of dyestuffs. 10,819. Apr. 22. (Ger., 22.4.26.)

Scottish Dyes, Ltd., Smith, and Thomas. Production of dyestuff intermediates. 10,501. Apr. 19.

IV. -Complete Specifications

*9197 (1927). I.-G. Farbenind. Manufacture of dyestuffs containing chromium. (269,522.)

*10,318 (1927). I.-G. Farbenind. Manufacture of diazo-sulphamic acids of the cyclic series. (269,582.)

*10,319 (1927). I.-G. Farbenind. Manufacture of compounds of aromatic para-diamines with sulphur dioxide. (269,583.)

V. -Applications

Barbon and Delaville. Treating residual liquors from treatment of cellulose material. 10,704. Apr. 21. (Fr., 21.4.26.)

Courtanlds, Ltd., Hazeley, and Hegan. Manufacture of artificial filaments etc. 10,736. Apr. 21.

Imray (I.-G. Farbenind.). Manufacture of cellulose esters. 10,499. Apr. 19.

Muller. Apparatus for continuously drying cellulosic materials. 10,951. Apr. 23.

Nobel's Explosives Co., Ltd., and Rintoul. Cellulose products. 10,500. Apr. 19.

Potts (Atack). Manufacture of paper. 10,396. Apr. 19.

Wells. Separation of vegetable fibrous material. 10,576. Apr. 20.

Yorkshire Dyeware & Chemical Co., Ltd., and Craven. Treatment of wool. 10,947. Apr. 23.

V.—Complete Specifications

14,192 (1926). Fish. Preparing paper pulp. (255,030.)

18,340 (1926). Soc. Fabr. Soie Rhodiaseta. Manufacture of artificial silk. (269,377.)

20,744 (1926). Fabricord, Inc. Obtaining fibres from flax, hemp, etc. (269,389.)

22,761 (1926). Heberlein & Co. Improving vegetable fibres. (258,598.)

*9684—5 (1927). British Celanese, Ltd. Manufacture of cellulose derivatives. (269,529-30.)

*10,028 (1927). Verein f. Chem. Ind. Treatment of precipitated acetyl cellulose. (269,543.)

VI. Applications

Brandwood. Fluid treatment of yarns etc. 10,386. Apr. 19.

Carmichael (I.-G. Farbenind.). 10,861. See IV.

Chem. Fabr. Mileh, and Landner. Dyeing fibres. 10,818. Apr. 22. (Ger., 23.1.25.)

I.-G. Farbenind. Dyeing and printing cellulose esters etc. 10,952. Apr. 23. (Ger., 23.4.26.)

Taylor. Bleaching-machines. 10,910. Apr. 23.

VII. -Applications

Gaillard. 10,827. See XVI.

Haddan (Stackable). 10,655. See XVI.

James (Merek & Co.). Colloidal iodine. 10,586. Apr. 20.

Stevens and Vantin. Manufacture of tin iodine compounds. 10,866. Apr. 22.

Urbain Corporation. Recovery of phosphorus etc. 10,699. Apr. 20. (Fr., 21.4.26.)

VII.—Complete Specifications

3594 (1926). Azogeno Soc. Anon., and Toniolo. Concentrating ammonium nitrate solutions. (247,229.)

4472 (1926). Aluminum Co. of America. Treatment of metallic oxides. (248,360.)

9939 (1926). I.-G. Farbenind. Manufacture of basic chromium salts. (251,267.)

26,917 (1926). Oesterreichische Chem. Werke. Production of persulphuric acid and its soluble salts by electrolysis. (265,141.)

*8741 (1927). Gerlach. *See* XI.

*10,039 (1927). I.-G. Farbenind. Recovery of sulphur from solutions of ammonium polysulphides. (269,546.)

VIII.—Complete Specifications

15,850 (1926). Scheidhauer & Gessing A.-G. Manufacture of clay-bonded products. (262,383.)

29,474 (1926). Quartz & Silice Soc. Anon. Blowing and moulding articles in silica glass. (263,766.)

IX.—Applications

Curtin. Preserving wood. 10,507. Apr. 19.

Montgomerie. Bituminous emulsions. 10,916. Apr. 23.

IX.—Complete Specifications

*9126 (1927). Soc. Le Xylum. Manufacture of magnesia cements. (269,518.)

*10,047 (1927). Portland-Cementwerk Balingen Ges. Manufacturing acid-proof hydraulic binding-agents. (269,549.)

X.—Applications

Carne. Soldering aluminium. 10,111. Apr. 19.

Marks (Kemel Laboratories Co.). Production of beryllium. 10,630. Apr. 20.

X.—Complete Specifications

1208 (1926). Lewin. Refining brass and bronze secondary metals and their residues. (269,253.)

4472 (1926). Aluminum Co. of America. *See* VII.

6328 (1926). Siemens & Halske A.-G. Electrolytic refining of copper. (264,116.)

7167 (1926). Dieker (Metals Protection Corp.). Protecting iron and steel against corrosion. (269,305.)

9203 (1926). Marks (Amer. Smelting & Refining Co.). Recovery of zinc from dross. (269,321.)

9536 (1926). Rushen (New Jersey Zinc Co.). Treatment of zinciferous materials. (269,324.)

12,073 (1926). Johnson (I.-G. Farbenind.). Manufacture of pure iron. (269,345.)

15,735 (1926). Lauber. Electric furnaces for the manufacture of aluminium. (256,193.)

25,723 (1926). British Thomson-Houston Co. Electroplating. (259,983.)

*22,465 (1926). Vulcan Detinning Co. Electrodeposition of tin. (269,474.)

*10,301 (1927). Goldschmidt A.-G. *See* XI.

XI.—Application

Lodge-Cottrell, Ltd., and Lodge. Electrical precipitation of small particles from gases. 10,941. Apr. 23.

XI.—Complete Specifications

6328 (1926). Siemens & Halske A.-G. *See* X.

11,391 (1926). Wade (Philips' Gloeilampenfabr.). Manufacture of oxide cathodes for discharge tubes. (269,341.)

15,735 (1926). Lauber. *See* X.

18,504 (1926). Automatic Telephone Manuf. Co., Ltd., and Farrant. Electrolytic cells. (269,378.)

18,865 (1926). Hart Accumulator Co., Ltd., and Hardy. Secondary electric batteries. (269,380.)

25,528 (1926). Seig. Accumulators. (269,344.)

25,723 (1926). British Thomson-Houston Co. *See* XI.

26,917 (1926). Oesterreichische Chem. Werke. *See* VII.

1418 (1927). Aletter and Strasser. Accumulators. (264,539.)

*22,465 (1926). Vulcan Detinning Co. *See* X.

*8464 (1927). Standard Telephones & Cables, Ltd. Magnetic core materials. (269,510.)

*8465 (1927). Standard Telephones & Cables, Ltd. Magnetic materials. (269,511.)

*8741 (1927). Gerlach. Cells with quicksilver cathodes for the decomposition of alkali chlorides. (269,513.)

*10,301 (1927). Goldschmidt A.-G. Production of aluminium conducting-material. (269,580.)

XII.—Complete Specifications

20,229 (1926). Erslev. Preparing fats of a plastic and pliable consistency. (269,384.)

*7790 (1927). Industrial Spray-Drying Corp. Manufacture of a finely-divided dry soap product. (269,506.)

*8960 (1927). Industrial Spray-Drying Corp. Manufacture of soap powder. (269,516.)

XIII.—Application

Johnson (I.-G. Farbenind.). Production of coloured brushwork lacquers. 10,482. Apr. 19.

XIV.—Applications

Dunlop Rubber Co., Ltd., and Twiss. Manufacture of rubber etc. 10,421. Apr. 19.

Scheithaur. Regenerating rubber. 10,659. Apr. 20. (Ger., 8.5.26.)

XV.—Application

Technicolor Motion Picture Corp. 10,523. *See* XXI.

XVI.—Applications

Gaillard. Treating superphosphates. 10,827. Apr. 22. (Spain, 22.4.26.)

Haddan (Stackable). Production of ammoniated superphosphate. 10,655. Apr. 20.

Ialhenroth. Producing soluble phosphates. 10,577 and 10,615. Apr. 20. Producing mixed manures. 10,596. Apr. 20. (Sweden, 20.1.27.)

Selbi Soc. Manufacture of fertiliser. 10,820. Apr. 22. (Fr., 16.10.26.)

XVI.—Complete Specification

513 (1926). Johnson (I.-G. Farbenind.). Manufacture of mixed fertilisers containing nitrates. (269,235.)

XVII.—Application

Kienzle. 10,519. *See* XIX.

XVII. Complete Specification

177 (1926). Steffen. Obtaining tricalcium saccharate. (261,693.)

XIX.—Applications

Avanzi. Preparation and preservation of fish etc. products. 10,842. Apr. 22. (Italy, 22.4.26.)

Kienzle. Manufacture of flavouring etc. substances from sugar cane. 10,519. Apr. 19.

XIX.—Complete Specification

*10,292 (1927). Woo. Manufacture of edible substances. (269,576.)

XX.—Applications

Abraham. Production of material containing thymol and polymerised formaldehyde. 10,528. Apr. 19.

Higgins, and United Water Softeners, Ltd. Production of sterilising-agents etc. 10,845. Apr. 22.

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence) 35, Old Queen Street, London, S.W., has received the following inquiries for British goods: British firms may obtain further information by applying to the Department and stating the specific reference number: *Australia*: Cutlery (390); Wire-woven asbestos packing, polishes, japan and varnish finishes (405); Steels (A.X. 4608); Drugs, chemicals, pharmaceutical preparations (437) *Austria*: Belting, rubber goods (411). *Belgium*: Shellac (412). *British India*: Copper conductors (B.X. 3469); Steel tyres, best Yorkshire iron (South Indian Railway Company, Ltd., 91, Petty France, London, S.W.1). *Canada*: Chinaware, earthenware, glassware, (C.X. 2279). *Dutch East Indies (Java)*: Pig lead (A.X. 4606) *Egypt*: Metal polish, blacking, paint, oils, greases, acids, leather, copper hardware, ironmongery, belting, mild steel, galvanised plates (C.X. 2268). *France*: Iron and other metallurgical products (393); Oilseeds (414). *Mexico*: Chinaware (428). *Peru*: Piping, filtering plant (A.X. 4186) *South Africa*: Motor spirit (B.X. 3454); Paraffin oil (B.X. 3453). *Uruguay*: Paper and cardboard (B.X. 3135).

Vertical Retorts

The Aberystwyth Gas Company has placed an order with the Woodall Duckham Vertical Retort & Oven Construction Company (1920), Ltd., for a Woodall-Duckham continuous vertical retort plant, comprising 8 unit retorts having a total carbonising capacity of 40 tons per day. The installation is complete with coal breaker and elevator, producer coke hoist, and waste heat boiler of the vertical type.

Coricol Finishes

The British Dyestuffs Corporation, Ltd., has recently issued a pattern card illustrating shades on leather which may be obtained by the use of Coricol Finishes. Following upon the sale of Necol Leather Finishes (formerly marketed by Nobel Chemical Finishes, Ltd.), Coricol Finishes have been introduced to meet the demand for grain finishes which do not obscure the

grain, but assist in the production of even shades of colour on irregular stock. Coricol Finishes are capable of giving a coloured finish which is absolutely fast to damp and rubbing and at the same time of extreme fastness to light. These qualities are secured by incorporating suitably coloured organic pigments with nitro-cellulose varnishes. They can be applied to all classes of grain leather, but are primarily intended for spraying on coloured leathers. Drying is accomplished quickly. After skins treated with Coricol Finishes have been aired for a while, they may be grained, ironed or lightly glazed. The present Coricol Finishes include Scarlet R, Yellow G, Black R, White, and Brown A, and two mode shares of Coricol Fawn S and O. With these products it is possible to match practically all the shades at present in demand for the shoe trades. Other additions will be made at a later date. The pattern card describes the application of the finishes.

EDITORIAL

Industrial Conditions in America

WE are glad to publish this week a short article by the Rt. Hon. Tom Shaw commenting on the report of the delegation recently appointed to study industrial conditions in the United States and Canada. Mr. Shaw is a Member of Parliament who is well acquainted with the industrial conditions in this country, in America, in several European countries and some Asiatic countries. He has travelled widely and made a special study of labour conditions; he was Minister of Labour in the last Government, and he speaks with an authority on industrial matters which gives his remarks considerable importance. We are therefore sure that our readers will be attracted to his article and glad to read it. Mr. Shaw compares, as we all do, the United States with the United Kingdom, it is useful to do this if we remember the many factors which require consideration, but it would be even more instructive to compare the United States, a partially developed continent, with another partially developed continent, the Disunited States of Europe. We in Europe have done much to cause unnecessary disunion, and it is very difficult to see how much of this disunion could have been prevented. It is part of our task as scientific men to do something to promote community of interest between ourselves and our various neighbours, and this is one reason why we think the meetings of the International Union are of such value. The chemical industry has many ramifications and many bonds linking the industry of this country with the industries of other countries. The soda industry, the dyestuffs industry, and several other branches of the chemical industry provide opportunities for pooling of knowledge, such as Mr. Shaw advocates, and for community of interest between the manufacturers of Britain, France, Germany, and America. Imperial Chemical Industries, Ltd., and its allies on the Continent may in time form an organisation powerful as a peace factor, but, nevertheless, powerless when angry passions sway the cabinets and peoples of Europe. The concluding words of Mr. Shaw's article are an earnest appeal for peace in industry. In this

country we have had a long period of strife and the financial loss occasioned by strife, culminating in the events of last year, the effects of which we shall long feel. As the balance sheets at the end of last year are being published, they make melancholy reading. The sacrifice of energy and money was very nearly futile, and it will require all the advocacy of such men as Mr. Shaw to prevent a recurrence of this disastrous experiment. People who are compelled by circumstances to meet frequently have only to assume that those they meet are rogues to ensure foolish and disreputable treatment. Mutual distrust between employers and workers is the cause of much of our trouble, and it is not very material at the moment to consider whether the distrust is justified or not. It is our business to make sure that the distrust in the chemical industry, at any rate, is not justified and does not exist. We have a good record in the chemical industry, and we ought to keep it; we shall keep it if we, on both sides, exercise ordinary good sense and fair play. Mr. Shaw has alluded to unemployment, to increased production, and to the elimination of waste. It is quite probable that many of our readers may hold political opinions which differ from those of Mr. Shaw; few will dissent from his view that the two sides in industry should have greater confidence in each other. We have given distrust, strife, stoppage of work and waste of time and energy a fair trial; suppose we try the effects of increasing trust, a little patience, fair play, and a recognition of the fact that most employers and most workers have their good points. We can easily begin this in the chemical industry, for we are already half-way there.

The Chemical Engineering Group

The Proceedings of the Chemical Engineering Group, Vols. VIb and VII, 1924, 1925 have just been published. They include many interesting papers; in 1924 there were two papers on crystallisation by Mr. Hugh Griffiths and Mr. T. V. Barker, which we thought were unusually interesting, and two papers by Mr. F. M. Potter and Mr. H. C. Marris on chemical works costs, which should

be useful to many chemists; in 1925 are several papers on fuel questions, including some of the smokeless-fuel papers read at Leeds in July, 1925. The list of all the papers in 1925 is a long one, and we can here mention a few only: one by Mr. David Brownlie on "Steam generation under critical conditions"; "The internal-combustion boiler," by Mr. Oscar Brunler; "The treatment of solvents used in dry cleaning," by Prof. J. W. Hinchley; "The combustion of sulphur-containing materials," by Mr. P. Parrish; "Smokeless fuel," by Dr. C. H. Lander and Dr. Margaret Fishenden; "Solid smokeless fuels," by Mr. E. C. Evans; and "A study of tar," by Mr. F. S. Sinnatt and Dr. J. G. King. Many of these and the other papers are of considerable importance; they make a handsome volume of 200 pages. Some of the papers have already appeared in this JOURNAL, but others are now published for the first time. We were glad to see in Mr. T. V. Barker's paper a couple of correct drawings of copper-sulphate crystals; many incorrect drawings of these crystals were published sixty and less years ago which still find their way into modern text-books, and it is singular that so common a substance should have received such treatment. In the old days, when many compounds were prepared in tubs in the back yard, applied chemistry was often merely large-scale chemistry, and involved but little knowledge of engineering. The time will come when chemical engineering will not only be essential to applied chemistry, but will, so far as the manufacture of chemicals is concerned, be very nearly identical with it. We do not ourselves see how anyone who is concerned in the manufacture of chemicals on the large scale can dispense with this volume of proceedings, and we think the Society and the Group have every reason to be proud of it. Our satisfaction with the Group and its activities is tempered by the news that Mr. Talbot is retiring from the post of Honorary Secretary. Mr. Talbot will still take a keen interest in the Group, but can no longer spare the time to attend to so much detail as his office has involved. Mr. Talbot is a Leeds man, and that, obviously, implies a good deal of energy and determination; he has, however, shown these qualities to a greater extent than could be expected even from a native of that great city. He has devoted much time to the Group, has helped it enormously, and enlivened it by the vigour of his actions and speech. His methods have been breezy rather than unctuous; he has wasted neither his own time nor the time of other people, and he will be very much missed. He has seen the Group become an important organisation, and taken a leading part in making it important. When we consider the record of solid achievements of the Group, it is surprising to remember that its foundation was so recent as in 1918, when about seventy gentlemen met in Cheapside to discuss its formation. At that meeting Mr. Talbot was appointed to act as recorder of the proceedings, and ever since he has acted as the Group's Honorary Secretary. He can look back with pride on the part he has played in the rapid development of the Group, and everyone will agree with the wisdom of retaining his services by including him in the Committee. We are glad that he has done so much, and are sorry that he cannot continue to do it.

INDUSTRIAL CONDITIONS IN THE UNITED STATES AND CANADA

By THE RT. HON. TOM SHAW, P.C., C.B.E., M.P.

The Report of the delegation which was appointed to study industrial conditions in the United States and Canada is indeed both interesting and intriguing. There is one omission which is very important. Not a word of the Report refers to the fact that prohibition is, theoretically at any rate, in operation in the States, and there is no attempt to show what effect it has had on industry, or how the purchasing power which formerly went into the channels of the "trade" now finds an outlet. Perhaps the delegation considered discretion the better part of valour so far as such a hotly-contested question is concerned. When, however, attention has been called to this omission, a frank expression of admiration for the conciseness and suggestiveness of the Report may be permitted.

I do not think we can copy either America or any other nation too slavishly, but certainly one or two facts pointed out by the delegation will repay consideration.

We ought never to forget certain advantages possessed by the United States. The delegation, on pages 10 and 11, show how vast the territory of the States is. Three million square miles, a spread of nearly 20 degrees of latitude and 60 degrees of longitude, with all kinds of climates, soils, minerals, and other natural resources; these, indeed, form a formidable list. Add to them the fact that between State and State there are no irritating and time and effort-wasting tariff barriers and hindrances to trade, and the possibilities of prosperity in the States seem to be boundless. In my opinion, even what is generally considered a drawback may be another source of strength. I refer to the mixed races of immigrants America has received. There may be a disadvantage in making the country a huge tower of Babel, but people who have the pluck and initiative to emigrate are in general the strongest and most self-reliant of their race, and a nation receiving the strongest and most adventurous of other races cannot fail to derive at least some benefit.

The Report shows that the States still remain largely agricultural, the last census showing one-third of the population working the land. This huge home market is of tremendous importance when the industrial position is considered. Its existence can never be left out of account by a serious student of industrial and economic conditions.

On page 12, the Report comes seriously to grips with a tremendously important question. The delegation say, in effect, that the employers in many industries which were badly hit after the 1921 depression found that wages reductions as a policy were bad, and turned rather to increasing efficiency and production, a reduction of costs, and the maintenance of wages—"purchasing power" is the expression used by the delegation. *This led to a real increase of purchasing power, which has had a great effect.*

There is almost a touch of romance in the sensational development in electrical, building and constructional, transport and automobile work. These developments are shown to have led to incalculable advances in all

directions. I am left with the feeling that Americans see things in a bigger way than we do, and their mental horizon is wider.

Frankly, I cannot say I am favourably impressed by another American development discussed by the delegation. They speak of the buying on the instalment system, which has "become a marked feature of American life amongst all classes." Particularly do I remember from my own experience how some English working-class families have suffered through hanging millstones of debt round their necks by constantly buying on credit, and sinking deeper and deeper under the load. Credit buying and "instalment purchasing" I, personally, *do not* desire to see developed amongst our workers at home.

The picture painted by the delegation is certainly not altogether a garden of roses. In Appendix 9, attention is called to unemployment, and an estimate is made according to which the States had $3\frac{1}{2}$ millions of unemployed in the bad times of 1921. Speaking of even these times of high prosperity—as they have been described—the Report goes on to say:—"The Board (i.e., the National Industrial Conference Board) estimate that there is at any time about 1,750,000 unemployed, out of a total of 12,000,000 workers engaged in manufacturing industries." In a word, some $14\frac{1}{2}$ per cent. of workers idle, even in prosperous times, in a country where efficiency of management and volume of production are being envied, and sometimes copied, by other nations! In fact, the lowest estimate of unemployment appears to be $12\frac{1}{2}$ per cent., and "fluctuations . . . in the volume of unemployment appear to be greater than in Great Britain." What a picture!

There is, however, no doubt that when full wages are earned, the man who is a skilled worker gets much higher wages than here at home, and has also a greater chance of regular work than the huge mass of unskilled and semi-skilled workers which immigration has provided in such huge proportions in the States.

What particularly can the States teach us here at home? The Report, if carefully studied, will supply, if not a completely satisfactory answer, at least many important suggestions. First of all, may I refer to one which I personally consider very important.

On page 41 there is a paragraph dealing with the exchange of ideas, experiences, and information, even between competing firms. There is a very free and effective supply of information to Trade Associations and Chambers of Commerce which helps manufacturers better to estimate possibilities. The old British idea of every firm being a little world of its own, doing its work in its own way, and being proud of being absolutely self-contained, and having "no connection of any kind with any other firm," was all right when the world was struggling to get British goods. Now, *when the struggle is to sell British goods*, the old stupid, secret, individualist method of working, which desires to "have no connection with the other fellow," is sheer madness. Exchange of information and co-operation would revolutionise some British industries. Take agriculture for instance. I have never been in a town in an agricultural area yet where Danish produce of all kinds was not on sale. Why? Denmark has no perceptible advantage. Neither in soil,

transport, nor human material is she our superior. But in intelligence she is. Her farmers do not insist on working on century-old lines, every man buying, selling, and making up for himself. On the contrary, they co-operate, buy in bulk, make up on scientific lines, sell through their own agencies, pool knowledge, adopt scientific methods—and beat us hollow. If we will persist in every man "standing independently," working on expensive and out-of-date lines in his own small way, buying and selling as if the world had stood still since the days of the stage coach, paying huge sums for the transport of his produce because he cannot send a "full load," and similar "peculiarities," we shall lose our position in the world.

If there is one thing which stands out prominently in the Report, it is that the tendency of Americans voluntarily may even gladly, to scrap old methods and machinery for something better, is largely responsible for the admittedly enormous advance made. Small uneconomic concerns have to go. Old-fashioned, slow, and uneconomic methods are giving way to new, large-scale, and "standardised" industry. It may be regrettable that the old "personal touch" and individual design have to go. We have, however, talked an "infinite deal of nothing" about personal touch and individual design. There is clear undisputed evidence that in many American concerns run on the new lines the workers are nearer the management, and more active in suggesting improvements, than ever the workers have been in our "personal touch" firms. As to "individual design" and its twin brother, "excellence of manufacture," may I say I prefer American ways? So long as there are very rich people there will always be a limited market for individuality of design and super-excellence of craft work. Certainly, if I were personally rich, I would buy articles in which design and hand-work are at their best.

America has discovered—the word is not too strong—the huge purchasing strength of the people who could afford things when they became cheaper. The Ford car was perhaps the greatest pioneer in the race for the money of the poorer classes. Have we not a tendency at home to stick to individual design and super-craftsmanship, which only the very few can afford, forgetting that many purchasers at small prices may be better than a few at high prices? One must admit after reading the Report that the American manufacturer in many ways is superior to his British rival. He makes machinery do nearly all the hard, dangerous, and dirty work. He does not look upon a working man as worth only so many shillings a week, and cut his rates when he exceeds the sum. He seems perfectly satisfied to consider the amount a worker earns as not being the principal thing. If I may put it in my own way, what he pays is quite secondary to what he gets for what he pays.

He is generally, if I have read the Report rightly, not so "stick in the mud," not so individualist, not so hidebound, and rather more scientific than the bulk of our employers. As to the workmen, the Report says, "The fact that the American employer welcomes the British artisan above any other for his skill and reliability speaks for itself." A fine tribute to the often-maligned British worker. The reading of the Report does

not prove to me that America is a land of perfect industrial peace and harmony, or that it is Heaven for the workers. Strikes and lock-outs there are conducted often with a concentrated bitterness we do not know.

I am quite satisfied that in these islands we have workmen as good as, or better than, anywhere in the world, including America. But if we are to be prosperous we must be prepared to learn from America methods of scientific management, how to eliminate waste, and how to get efficiency in production.

Will the British worker be an obstacle to the introduction of newer methods and improved machinery?

That, in my opinion, depends on whether he has confidence that he will get a square deal. Let a body of employers say to their workers that, however much they earn, rates will not be cut if the utmost intelligence is used to increase production, and see what the result will be.

Whatever takes place a careful reading of the Report can only do good. It is idle to deny that British workers are suspicious—I personally think, with good reason. But just as employers must wake up if we are to go ahead, my own friends the workers must cease to assume that increased production means necessarily "taking it out of their bones." On the contrary, where hours are lowest, wages highest, and conditions best, is the greatest volume of production to be found. Eternal bickerings and strife lead to low earnings, loss of profits, and privation for the workers. Reason, fair play, and justified trust alone can be a foundation on which scientific improvements may be built. If the discussion of the Report helps the two sides in industry to get greater confidence in each other it will have done good. Without that confidence real development on scientific lines is impossible.

DRIERS AS APPLIED TO PAINT AND VARNISH*

By CLAUDE E. WATSON

To most people the term "drier" is quite familiar and is known as something that is added to paint and varnish to cause either to dry more rapidly. Driers have been used many years for this purpose, but it is only within the last few years that they have been investigated with a view to better understanding why and how they work in conjunction with paint and varnish. The lack of knowledge concerning these points has been the cause of many failures in otherwise protective coatings, due to their improper use. However, through careful investigation, the paint and varnish industry has learned that they must be handled with the same great care as powerful drugs are by the medical profession. When used in very small quantities they accomplish their work in a very efficient manner, but when used in excessive quantities they will generally cause destruction, and very efficiently too. Technically, these materials are not driers, but are accelerators of oxidation, and paint or varnish does not dry in the true sense of the word, but hardens up by a process of oxidation. However, throughout my paper, I will use the terms with which we are all familiar.

During the last six years we have done considerable experimental work with driers, and during this time have accumulated some very valuable information, both on theory and practical application. Our work has entailed many disappointments and much contradictory evidence due to variations over which we had no control, but by averaging results over long periods, we eventually arrived at results which are practical. The subject is one which both puzzles and fascinates, and while we have mastered many difficulties, we have much to learn yet. As time is short, I have endeavoured to make my paper a brief outline on both theory and practice. Some of the theories are given in the hope that they will be freely discussed with the object of pointing out weaknesses, because it is only through sincere criticism that facts are discovered and proved.

To understand the function of driers, it is first necessary to understand why a liquid film of paint or varnish changes to a semi-solid, dry film. Since linseed oil is used to the greatest extent in paint, and is the one oil that has been studied most, we will follow its drying mechanism as investigated by Friend, Weger, Morrell and others. The oil hardens by oxidation, which takes place at the unsaturated linkages of linolenic and linolic glycerides; the glyceride of linolenic acid takes on oxygen at its three double bonds and further oxidises to yield carbon dioxide, acetic acid, etc. The glyceride of linolic acid simply takes on oxygen at its two double bonds and does not yield volatile products. It is due to the oxidation of these two glycerides that the film hardens, because the other saturated glycerides present in linseed oil do not oxidise under normal conditions. These, along with the glycerol radical, help to keep the film soft. (It is the presence of excessive amounts of these saturated glycerides in soya bean, fish oils, poppy seed oil, etc., which cause them to be slow drying.) During the initial period of oxidation the oil absorbs molecules of oxygen rather than atoms forming peroxides, and there is very little change until the tenth hour. During this period the peroxides are formed; then the oil begins to change colour, owing, no doubt, to the action of these peroxides. These oils represent a raw linseed oil which has been subjected to 21 hrs.' blowing with air, which is quite similar to the drying process. The peroxides now accelerate the further oxidation of the oil quite rapidly, as is indicated by the increase in viscosity shown by the samples; they are therefore termed catalysers and the process is known as auto-oxidation, which is the process of combustion in air that takes place at a slow rate under normal conditions.

From the above it is not very difficult to understand just how the oxidation of the oil takes place. The next step is to understand how the film is formed. As the blowing process proceeds the viscosity increases, and after the tenth hour an emulsoid colloid is slowly formed in which the oxidised and partially oxidised portions of the oil are the disperse phase, while the unoxidised portions are the medium. As the process of oxidation goes on the oil becomes more viscous, because the phase is becoming greater and greater while the medium is becoming less and less. Since the phase is insoluble in the medium, internal surfaces are gradually developed which must rub against the liquid surrounding them or

* Read before the Ottawa Section on March 17, 1927, with the permission of the Ottawa Paint Works

against each other, causing the once limpid oil to become very viscous, until eventually the medium is so small that the phase can no longer be surrounded, and consequently the oxidised portions come in contact with each other, causing the film to set, so that it will not wet an object which touches it lightly. Following this period, continued oxidation gradually causes the film to set very hard, because with the medium practically eliminated, it requires quite a force to cause the particles to move about each other.

Linseed, china wood, perilla, soya bean, and fish oil will all act in the manner mentioned above by themselves; the last-named two dry very slowly, but when added in paint and varnish they are all too slow for practical purposes. Therefore it is to assist in these reactions that driers are used. Driers are compounds of metals which are soluble in oil with or without the aid of heat, and when added to paint or varnish cause an acceleration of the rate of oxidation. According to Van Wirt and Rhodes, the percentage of volatile products and the total oxygen absorption is the same with or without driers; therefore they simply accelerate the process. They may just assist in the formation of the peroxides or they may hasten the whole reaction throughout; in the former case they would be termed false catalysers, whilst in the latter they would be termed true catalysers. Catalysis designates those chemical reactions which by themselves proceed slowly, but are materially hastened when some foreign substance is added. I am of the opinion that the driers hasten the whole reaction, and therefore claim that they are catalytic in their action. To go thoroughly into this matter would require a paper by itself; therefore I will only deal briefly with theories which aim to prove this statement.

Since driers are in colloidal solution, they are in a very finely divided condition. Now, Wenzel's law states that the greater the absolute surface, the greater will be a chemical change; therefore reactions must occur quite rapidly at the surface of the driers, because, being in a finely divided condition, their absolute surface must be great. When an oil film containing drier is exposed to the air, oxygen is adsorbed by the drier, and as a result of this adsorption it is activated. This adsorption involved the temporary combination of the oxygen with the drier, not as a true chemical compound, but as an indefinite combination which is always varying as the oxygen is being used up in the reaction. For instance, when oxygen is adsorbed by cobalt, manganese or lead, oxides are not formed, because if this were so there would be no acceleration; we assume this, since it is very hard to dissolve the oxides of these metals in hot oil so that they will accelerate drying. As stated before, the result of this adsorption is simply that the oxygen is activated. After this it is taken up rapidly at the double bonds of the unsaturated glycerides, forming peroxides; then, by means of the combined action of these peroxides and the activated oxygen carried by the drier, the final process of oxidation is accelerated. The action cannot be called either physical or chemical, because it is accomplished by both physical and chemical means. We do know that heat alone will accelerate drying, as also will the ultra-violet light rays present in sunlight, there being no drier present.

From tests, we know that there is a decided difference in results obtained when using lead, manganese or cobalt driers. Lead is a weak drier, while manganese and cobalt are strong driers. It requires practically 50 parts of lead to accomplish the same work as 7 parts of manganese or 3 parts of cobalt, but in no case is the work accomplished in the same manner. From this, it is quite apparent that there is a decided difference in the adsorption and activating capacities of these three metals.

I have stated that the work of drying, using the different metals, is not accomplished in the same manner. When these metals are added to oil in proper proportions and then these oils are poured on glass slides, the oil with the lead drier gradually changes from a thin limpid oil to one which is very viscous; it then gradually becomes tacky, and then, by the end of the drying, it has set dry to the touch, but for a considerable time retains a slight tackiness. The other two oils, with manganese and cobalt as drier, do not show this gradual change, but remain in about the same limpid condition until near the end of the drying period, then the change through the viscous condition to the dry film with no sign of tackiness is a decidedly rapid one compared with the lead oil.

I believe the above actions are best explained by referring to the orientation theory regarding surface structure in organic liquids. The molecules in this class of liquid arrange themselves at the surface so that the least active portions are turned towards the vapour phase, whilst the most active portions are turned toward the liquid phase. When lead, manganese or cobalt are added to the oils in equal strengths, it is observed that the lead oil has a lower surface tension, and the manganese or cobalt oils have a slightly higher surface tension than the original oil. Therefore, it would be quite reasonable to believe that whilst the driers are distributed throughout the whole film, yet the manganese or cobalt oils contain no metal in the surface film, whereas the lead oil has metal present in the surface film. This being the case, when the films are exposed to air, because the manganese or cobalt are covered by a layer of inactive molecules, it takes considerable time for the oxygen to penetrate to the metal, but when it does reach the metal, the oxidation is rapid, on account of the high adsorption and activating capacities of these metals, with the result that the film is not dried throughout, but more towards the surface. With lead, because it is present in the surface film, it starts the process of adsorbing and activating oxygen at once, but on account of its low capacity, the process is gradual, with the result that the film is oxidised throughout, but in this process some of the lead salt is forced to the surface, and therefore leaves the dry oil with a tacky feel.

Since driers are oil-soluble compounds of metals which are capable of forming more than one oxide, providing that the salts of the higher oxides are less stable than the salts of the lower oxides, one can readily see that there are many metals capable of being used as driers, but because some lack efficiency and others are too expensive, only the compounds of lead, manganese and cobalt are used to any great extent; therefore, my discussion deals solely with these materials.

Driers fall within three general classes. There are the raw materials which are dissolved in oil directly; there are raw materials which are made by chemical processes; and, third, there are liquid driers, japan driers, etc., which are made from both of the raw materials. The first class includes litharge, red lead, and lead acetate, from which lead driers are made; manganese dioxide, acetate, carbonate, borate, sulphate, precipitated hydrate and recovered manganese, from which manganese driers are made; and cobalt oxide, sulphate and acetate, from which cobalt driers are made. The second class includes lead resinate and linoleate, manganese resinate and linoleate and cobalt linoleate and resinate, either fused or precipitated. In making the precipitated driers, an aqueous solution of the metallic salt is derived from either lead acetate, manganese sulphate or cobalt sulphate as the case may be. The oil or resin is made into a soap by boiling with caustic soda. The soap solution is now added gradually to the water solution while the mixture is agitated, the whole procedure being controlled as to temperature, concentration of the different solutions, etc. The fused driers are made by dissolving compounds of the first class directly in oil or resin by means of heat. They are much darker in colour than the precipitated driers, and contain a much lower percentage of metal, which makes them less popular. The third class includes japan driers, liquid driers, oil driers, grinding japans, etc., some of these names designating the purpose for which the drier is made. Some are simply solutions of metals in oil, others are these solutions thinned with turpentine or mineral spirits, whilst others are solutions in oils and resin or resin alone, thinned with turpentine or mineral spirits. I will not go into the manufacture of these materials: that information is available in literature dealing with paint and varnish. I will deal solely with their use and the results obtained.

For many years the raw materials of the first class were the only driers available to the paint and varnish industry, and in their use many opinions have been expressed as to the advantage of one compound over another, but of late years the advent of manufactured raw materials has given us driers which, in most cases, have more advantages than any of the old driers.

(To be continued)

CZECHOSLOVAK SUGAR PRODUCTION AND EXPORT

The British Commercial Secretary reports that, according to the Bulletin of the State Statistics Office, the Czechoslovak sugar production during the season 1925-26 was as follows:—Total number of sugar factories, 166 (of which 102 were raw sugar factories, 53 were mixed factories, and 11 were refineries); the total number of workers was 69,393; the area under beet cultivation was 307,405 hectares; sugar beet worked up, 8,824,175 t.; sugar production (in raw sugar equivalent), 1,507,344 t.; and export of sugar was 1,079,910 t. The amount of sugar beet grown in the 1926-27 season so far is estimated at 6,232,987 t., the total area under cultivation being 258,176 hectares.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, JULY 4 to 8, 1927 ACCOMMODATION

Members who intend being present at the Annual Meeting, and who have not yet booked their rooms, are strongly urged to do so without delay, as hotel accommodation in Edinburgh during July is being rapidly reserved.

No bedrooms are now available in the North British Station Hotel—the Headquarters of the Society.

Single room accommodation for both men and women is still available in the University Hostels. Immediate application for such should be made to the Hon. Secretary of the Section—Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

A list of other hotels was published in *CHEMISTRY AND INDUSTRY* for February 4, 1927, p. 105.

RAILWAY FACILITIES

The Railway Companies of Great Britain (except the Metropolitan, the Metropolitan District, and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one-third for the double journey to persons travelling to Edinburgh to attend the meeting. Tickets will be available from Saturday, July 2, to Saturday, July 9.

It is urgently requested that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

BRITISH CHEMICAL ABSTRACTS INDEX, 1926

The Index to the Abstracts for 1926, covering both Pure and Applied Chemistry, is now ready, and copies are being distributed by the printers to members of the Society and subscribers to the *JOURNAL*.

CHEMICAL ENGINEERING GROUP

The annual business meeting was held on May 6 at the Imperial College, Mr. F. H. Rogers presiding.

In his report on the work of the previous year the Hon. Secretary, Mr. H. Talbot, was able to report another successful year of work and of increasing membership. The membership at the end of 1926 was 447, compared with 430 the year before. During the year the General Committee had held 10 meetings—all well attended and meetings of the Data Sheet and other sub-committees had also been held.

A number of important papers had been read at the meetings in 1926, many of which were joint meetings, either with various sections of the Society, or with other bodies, such as the Institution of Chemical Engineers etc. The paper read before a joint meeting of the Group and the Institution of Chemical Engineers on the "Beet sugar industry," on April 14, 1926, proved to be extremely interesting, and was followed on April 16, 1926, by the visit of a large party to the Kelham factory, near Newark. The best thanks of the Committee and members of the Group were due to Mr. Alfred Wood, Secretary of the British Sugar Beet Society, and to Mr. Kwantes and his colleagues, who made the meeting and the visit so thoroughly interesting and enjoyable.

During 1926 the outstanding event in the Group's work was the Congress of Chemists held in London under the auspices of the Society of Chemical Industry, and with the co-operation of the General Committees or Councils of a number of other bodies. The members of the General Committee of the Group assisted in the organisation of the Congress, and the Chairman of the Group, Mr. C. S. Garland, who was also Chairman of the London Section, presided over the deliberations of the principal Executive Committee responsible for the details of the Congress. The Group Committee wished to place on record their high appreciation of the most excellent results accruing from the arduous duties devolving upon Mr. Garland and the members of the Executive Committee and the special committees associated with him. It was safe to say that no more successful gathering of British chemists had been held in the history of chemical organisation in this country.

Special attention was also called to the conferences on "Fuel" subjects, completing the series inaugurated in July, 1925, with the meeting in Leeds. Largely as a result of this series of meetings, a new branch of the Society—the Fuel Section—was formed early in 1926, and the Hon. Secretary of the Group acted as one of the Joint Hon. Secretaries of the new Section. This "Fuel Section" of the Society, which now charges itself with the development of meetings of this kind, was advancing with rapid strides, and bade fair to become one of the most important branches of the Society's activities.

The Group had maintained and extended its relations and its joint meetings with other Societies and learned bodies, and it was no exaggeration to say that a larger spirit of co-operation was becoming apparent among scientific and technical workers than ever before existed. This was initially of advantage to those concerned, and ultimately must react beneficially upon the nation's industrial progress.

The balance sheet for 1926 again showed a small credit balance, and it was a source of satisfaction to the Committee to find that whilst no curtailment of their activities had been necessary, the support received on the way of members' subscriptions and from the parent Society was adequate to enable them to complete the year's programme. The Committee was grateful to the Council of the Society for the assistance extended to the Group's work.

The Committee wished to record their thanks to the Assistant Secretary, Mr. Mackie, and the office staff associated with him for their help in carrying on the work of the Group during the year.

The Data Sheet Sub-Committee had held several meetings during the year, and five data sheets were almost ready for issue. It was regretted that it was not possible to complete any of these for printing during the year 1926.

The volume of "Proceedings" for the second half of 1924 and 1925 was prepared for publication during 1926, but issue had to be deferred, owing to various difficulties regarding illustrations, until early in 1927.

In conclusion, the Committee wished to express their sincere thanks to the members of the Group for the increasing interest being expressed in the work. It was hoped that a further access of membership and an even

more successful year of effort would be experienced during 1927.

The following officers of the Group were elected:—Chairman, Prof. E. C. Williams, M.Sc., M.I.Chem.E.; Hon. Secretary, H. J. Pooley, M.I.Chem.E.; Hon. Treasurer, F. A. Greene, M.I.Chem.E. Major V. F. Gloag and Messrs. P. Parrish, D. Rider, H. Talbot, and A. J. V. Underwood were elected to fill the vacant places on the Committee due to the retirement of Messrs. S. G. M. Ure, E. W. Smith, T. W. Stainer Hutchins, and F. M. Potter.

Warm regret was expressed at the retirement of Mr. H. Talbot from the General Secretaryship of the Group, which he has held since its inception. Special resolutions were carried to express the gratitude of the Group for the invaluable work which Mr. Talbot has done so long for the Group.

After an informal dinner, Dr. W. R. Ormandy read a paper entitled "Chemical fire extinguishers." Dr. Ormandy traced something of the history of fire-fighting in London, and showed how the present-day fire brigade organisation came into being. He then discussed the main groups of fire extinguishers, dealing with soda and acid extinguishers, the carbon tetrachloride group, powder extinguishers, and the more modern utilisation of a foam blanket. The paper will appear shortly in CHEMISTRY AND INDUSTRY.

LONDON SECTION

The Annual Meeting was held in the Chemical Society's Rooms on May 2, Mr. C. S. Garland (Chairman of the Section) in the chair.

The report of the committee for the session 1926—27 stated that 9 meetings had been arranged during the session, and the Section had been fortunate in securing a number of prominent chemists to give accounts of recent developments in various departments of chemical industry. The list of papers was given. The average attendance at the meetings had been 74. The chairman said he believed this was a record, and one of which the committee was proud.

Since the last Annual Meeting of the Section the first Congress of Chemists held in this country had taken place in London, in July of last year, in conjunction with the Annual Meeting of the Society of Chemical Industry, the Society having accepted the joint invitation of the London Section and the Chemical Engineering Group to hold the meeting in London. The Executive Committee was composed of representatives of the London Section and the Chemical Engineering Group, with whom were associated representatives of other chemical organisations. It was generally recognised that this congress was an unqualified success.

The report stated that Mr. C. S. Garland was due to retire from the chairmanship, and the committee had elected Mr. W. J. A. Butterfield to fill the office of chairman for the ensuing session. Dr. G. W. Monier-Williams had expressed his wish to retire from the secretaryship owing to pressure of other work. The committee had to express to Dr. Monier-Williams their grateful thanks for and appreciation of his splendid work as Hon. Secretary of the Section for the past seven years. They felt that the present activity of the Section was largely due to the able way in which he had con-

ducted its affairs, and his ready inspiration in obtaining suitable subjects and authors for the many interesting papers that had been presented during his period of office. The Committee had elected Dr. R. T. Colgate in his place.

The members of the Committee to retire under Rule 7 were Mr. W. H. Coleman, Mr. J. A. Reavell, and Mr. W. G. Wagner. The Committee had also accepted, with regret, the resignation of Dr. W. Cullen. The following nominations had been received:—Dr. T. H. Durrans, Dr. G. W. Monier-Williams, Mr. S. G. M. Ure, and Mr. A. J. V. Underwood. Mr. F. H. Carr retired from the Committee in October, owing to his election as President of the Society, and the Committee had elected Prof. G. T. Morgan to fill the vacancy. Prof. Morgan was now nominated for re-election.

The Chairman formally declared the following elected:—Chairman, Mr. W. J. A. Butterfield; Hon. Secretary, Dr. R. T. Colgate; Committee Members, Dr. T. H. Durrans, Dr. G. W. Monier-Williams, Mr. S. G. M. Ure, and Mr. A. J. V. Underwood. The re-election of Prof. G. T. Morgan to the Committee was also confirmed.

The Chairman proposed that the Section should express its sincere thanks to Dr. Monier-Williams, in view of his retirement from the office of Hon. Secretary, for the manner in which he had conducted the affairs of the Section for the past seven years. The secretaryship, he said, was no easy task, and few realised the amount of hard work which was necessary on the part of Dr. Monier-Williams in order to ensure that things ran so smoothly, and in order to secure the papers which members had enjoyed. The success of the Section was due very largely to the work of Dr. Monier-Williams, and he asked the members to express as heartily as they could their very sincere thanks for all Dr. Monier-Williams had done during the past seven years. The vote of thanks was accorded with acclamation.

Dr. Monier-Williams, responding, expressed appreciation of the Chairman's remarks, and of the manner in which the vote of thanks had been accorded. After thanking the Chairman and Committees with whom he had served, he said the Section was to be congratulated upon having secured the services of Dr. Colgate, and he was perfectly certain that in Dr. Colgate's hands the Section had a bright future.

Mr. W. J. A. Butterfield proposed a vote of thanks to Mr. Garland for his very able conduct of the affairs of the Section during the past two years. No one could have performed the duties of Chairman better than he had done; the organisation of the Annual Meeting of the Society, in the hands of the London Section, was supervised by him in the most capable manner, and the arrangements were carried out in a manner which redounded to the credit of the Section and of the Society.

Dr. B. Dyer seconded the vote of thanks, which was accorded with enthusiasm.

Mr. Garland, responding, said his two years of office as Chairman had been a period of unalloyed pleasure, not only because the work itself had been so pleasant, but also because he had had the loyal help and co-operation of a number of men who had been good enough to cover up his deficiencies, and perhaps make the most of his few virtues. His interest in the Section in the future

would not be less than it had been in the past, and he hoped he might have the privilege of serving the Section in future in some humbler capacity.

At an ordinary meeting which followed the Annual General Meeting, a paper on "Recent investigations on contact insecticides" was presented by Mr. F. Tattersfield and Mr. C. T. Gunningham.

The authors, after defining the term "contact insecticides," gave a description of the work carried out at Rothamsted on this subject, with brief references to the researches of other investigators. A quantitative evaluation of the toxicity by contact of various substances, at a series of concentrations, was obtained with a special apparatus. The authors described the results obtained for a number of different tropical plants used as fish poisons. Derris, White and Black Haiari were shown to have insecticidal values of a high order. "Tubatoxin," the chief constituent of all three of these plants, has been proved to have a very high toxicity to certain adult insects. Various species of *Tephrosia* were also shown to be toxic, although not quite of the same order of toxicity as the above. The extracts of all these plants were stated to render foliage repellent to certain caterpillars. The authors also gave a full account of the toxicity of many series of synthetic organic derivatives to *A. rumicis*, the common black aphid on broad beans, and various insect eggs.

After references to the recent work of Richardson and Smith on the dipyrityls and to Siegler and Popenoe on the fatty acids, the group of fatty acids was dealt with at some length. It has been found that for this group toxicity increases on ascending the series up to the acid containing eleven carbon atoms, after which there is a decline. Toxicity disappears at tetradecylic acid (myristic). An analysis was made of the bearing of certain physical properties on the toxicity of fatty acids. None of these, however, were found to account fully for the values obtained.

The authors concluded that, so far, no simple generalisation has been discovered, capable of explaining the variations in insecticidal action, and it was considered that the next advance would come from work of a more detailed physiological character. Field trials which have been carried out with some of the substances discussed indicated that some of these were yielding important confirmation of the laboratory experiments.

OTTAWA SECTION —

At the regular meeting of April 21, presided over by Mr. A. E. MacRae, the first paper was entitled "The electro-plating and electro-refining of nickel," by Mr. W. C. Gardiner. This was the winning essay for the prize offered by the Ottawa Section to students in chemistry and chemical engineering of Queen's University, Kingston, Ontario.

Electro deposition of nickel is the basis of two important Ontario industries, viz., nickel refining and nickel plating. Although the principles of these two are similar, the ends in view are different, as is also the technique. A pure thick deposit is sought in refining, whilst in plating a thin (0.001 in.) protective coat of good appearance is aimed at. The quality of the deposit is largely determined by its physical structure.

and a knowledge of the factors influencing the latter is a necessary aid in arriving at desirable deposits; however, all these factors are not yet known. Among the known ones, the speaker discussed those which follow and which are the main factors.

1. *Current density*: this may only be increased to a certain point, after which poor deposits result.

2. *Concentration and agitation*: either of these leads to an increase of the metal content of the solution at the cathode and so allows the use of higher current densities.

3. *Temperature*: will allow higher concentration of solutions, increase the conductivity and decrease the occlusion of hydrogen.

4. *Conductivity*: increased conductivity reduces power costs and also tends to reduce the tendency to form "tree" deposits.

5. *Metal ion concentration*: controls the fineness of grain.

6. *Hydrogen ion concentration*: optimum values have been determined and running checks can be carried out colorimetrically.

7. *Addition agents*: colloids and reducing substances which influence structure of deposits, but do not affect 1-6 and 6 above.

8. *Structure of base metal*: may lead to defective deposits.

9. *Metal distribution and throwing power*: in irregularly shaped cathodes all parts are not equally distant from the anode so that the nearer portions receive higher current densities, the metal distribution not being uniform.

Consideration was given to the choice of bath constituents and the functions of these in plating, the composition of the anodes, operating conditions and also plating on zinc, aluminum and die castings.

Two electrolytic processes are being used for refining nickel, viz., the Hybinette and one used by the International Nickel Co. The main points of each were given. In both a nickel of high purity is obtained electrolytically, but in one the refining is electrolytic throughout with a high recovery of precious metals, whilst in the other metallurgical (furnace) methods are used to a greater extent and the recovery of the precious metals must be a further separate operation.

Mr. G. E. Grattan next presented a paper on "Seed analysis." The production of foodstuffs is as yet Canada's basic industry; control of weeds and seeds is therefore essential to agriculture. Control in Canada dates back to 1902, and last year some 60,000 samples were examined. This has led to decentralisation of the work. Samples are tested for purity and germination value by either the Irish or the Continental routine.

According to whether the seed is for home or export use. In the main the work is done by girls employed seasonally; these employees must be familiar with many hundreds of seeds. A representative weight of the well-mixed seed is picked over, the weed seeds removed, identified and counted. Thus, the purity is determined. For germination tests an average sample is placed between blotting paper or on cloth, soil or sand in an electrically controlled germination chamber, the moisture, heat and air supply being regulated and the number of viable seeds counted after various periods. Attention is also given to the value of growth.

Some seeds seem to have a "dormancy" period, and must be ripened in an oven before attempting to germinate them. Others show a retarded germination due to their being impervious to moisture until the outer covering is broken in some manner; these are scratched before putting in the germinator. Field experiments are used to determine whether there is ability to stand the Canadian winter and, also, if the plant is true to type. As some of these tests need 28 days to complete, research is under way to determine viability by the catalase content of the seed, and results so far are promising.

A hearty vote of thanks was accorded both speakers, and Mr. Gardiner conveyed the thanks of the Queen's Student body to the Ottawa Section.

CALENDAR OF FORTHCOMING EVENTS

- May 13. ASSOCIATION OF ECONOMIC BIOLOGISTS, Imperial College, Prince Consort Road, South Kensington, at 2.30 p.m. (1) "Principal plants yielding alkaloids," by Lieut.-Colonel A. T. Gage. (2) "Biochemistry of the alkaloids," by Dr. T. A. Henry. (3) "Medical aspects of the alkaloids," by Dr. J. Trevan.
- May 18. CHEMICAL SOCIETY, Theatre of the Royal Institution, 21, Albemarle Street, W., at 5.30 p.m. The Faraday Lecture entitled, "Problems and methods in enzyme research," by Prof. Richard Willstätter.
- May 18. INSTITUTE OF CHEMISTRY, Belfast and District Section. Annual General Meeting. Royal Belfast Academical Institution.
- May 18. ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY, Northampton Polytechnic Institute, St. John Street, Clerkenwell, E.C.1, at 7.45 p.m. "Protective effects of metal deposits on iron," by S. Wernick.
- May 18 & 19. SOCIETY OF GLASS TECHNOLOGY. On May 18, Special General Meeting in University College, Gower Street, London, W.C.1, at 2.30 p.m. Also Ordinary General Meeting at 2.40 p.m. (1) "The decomposition of glass by water at high temperatures and pressures," by Dr. G. W. Morey and Dr. N. L. Bowen. (2) "Brittleness of glass," by Prof. G. Gephloff. (3) "The new British 15-arm automatic suction bottle machine," by F. Redfern. (4) "Standard durability tests for bottles." The ninth Annual Dinner will be held in the Hotel Cecil, Strand, W.C.2, on May 18, at 7 for 7.15 p.m. On May 19, at 2.30 p.m., a general discussion will be held on "Furnace efficiency." In particular the discussion will be continued on the paper presented by Prof. W. E. S. Turner to the April meeting, on "A brief review of furnace developments." On the morning of May 19, a visit has been arranged to the Lamp Works of the General Electric Co., Ltd., Brook Green, Hammersmith, W.6.
- May 19. SOCIETY OF CHEMICAL INDUSTRY, Nottingham Section. Visit to the soap works of Messrs. Gerard Bros. at New Basford, at 2.45 p.m. Time permitting, a tour of the works will be followed by a short meeting, at which Mr. T. H. Gray will deal with some general considerations concerning the manufacture etc. of soaps.
- May 19. CHEMICAL SOCIETY, Burlington House, Piccadilly, W.1, at 8 p.m. Ordinary Scientific Meeting. "New developments in the study of acid catalysis: the catalytic catenary," by H. M. Dawson.

CHEMICAL SOCIETY

Thirty-nine new Fellows were elected by ballot at a meeting on May 5. The President, Prof. H. Brereton Baker, C.B.E., F.R.S., reminded Fellows that on May 18, at 5.30 p.m., at the Royal Institution, Albemarle Street, W.1, Prof. Dr. Richard Willstätter will deliver the Faraday Lecture, entitled "Problems and methods in enzyme research", admission will be by ticket only. At the ordinary scientific meeting on May 19, Prof. H. M. Dawson will give an account of his investigations on "New developments in the study of acid catalysis. The catalytic catenary." Applications for Research Grants must reach the Assistant Secretary not later than June 1.

Prof. C. K. Ingold discussed:

The nature of the alternating effect in carbon chains. Part XVIII. Mechanism of exhaustive methylation and its relation to anomalous hydrolysis. [With W. Hanhart.]

THE mechanism previously proposed (J., 1926, 1305) in connection with anomalous hydrolysis is shown to be applicable to exhaustive methylation and to the decomposition of quaternary ammonium compounds generally. In particular, (a) it accords with the formation of olefines in the absence of an α -hydrogen atom; (b) it embraces the generalisation ("Hofmann's rule") that ethylene is preferentially eliminated, and predicts the existence of exceptions and border-line cases; (c) it defines and explains the conditions governing the replacement of olefine elimination, the "primary reaction," by the elimination of methyl or another alcohol, the "secondary reaction"; (d) it embraces the different modes of decomposition of hydroxides and chlorides and leads to the deduction that other salts will furnish intermediate phenomena in an approximately regular series.

Prof. R. Robinson, in a written communication, observed that the formation of ethylene derivatives by all the usual methods was primarily due to the tendency of some atom (Br') or group (NR_3, OH_2 , etc.) to hold to its electrons. The general displacement caused by the group confers acid character on the substance, and for obvious reasons the proton is normally detached from the β -position. Occasionally, however, it leaves the α -position (e.g., the formation of stilbene derivatives) and in rearrangements of the borneol—camphene type it is detached by anions or anionoid neutral molecules from the γ -position. This is doubtless the explanation of the method of formation of *isosafrole* recently observed by Baker and Robinson, and a prediction based on this hypothesis is at present being tested. They anticipate the new molecular rearrangement:

etc. The effect of the phenyl group and of other substituents on the course of the formation of ethylenes is considered from the point of view of the theory of general electronic displacements.

Prof. Ingold replied that he agreed that the tendency of the substituent to hold electrons was in all cases an important factor, but this, in his opinion, did not involve that the mechanism was the same, e.g., in the elimination of hydrogen bromide by the action of alkalis, and in

exhaustive methylation. The stabilising action of group, even in cases where no α -hydrogen atom is present, is different in the two cases.

Prof. H. Bassett discussed:—

The inter-relationships of the sulphur acids. [With R. G. Durrant.]

THE hydrolysis of sulphur probably takes place in accordance with the reaction $\text{S}_2 + 2 \text{HOH} \rightleftharpoons \text{H}_2\text{S} + \text{S(OH)}_2$. The sulphylic acid cannot be isolated because it readily decomposes to yield hydrogen sulphide and sulphurous acid. This decomposition has been shown to occur both in acid and alkaline solutions by experiments with sodium formaldehydesulphoxylate and with sodium hyposulphite. Formation of sulphylic acid is considered to be the first step in the Wackenroder reaction.

Thiosulphuric acid decomposes in three different ways:—(a) to yield sulphurous acid (or probably sulphonic acid) and sulphur according to the bimolecular reaction $2\text{H}_2\text{S}_2\text{O}_3 \rightleftharpoons 2\text{H}_2\text{SO}_3 + \text{S}_2$, (b) to yield hydrogen sulphide and trithionic acid, and (c) to yield an anhydro-acid $\text{H}_2\text{S}_4\text{O}_5$. Decomposition according to (b) is considered to be the fundamental reaction by which polythionates arise—both in acidified thiosulphate solutions, and in the Wackenroder reaction, whilst trithionic acid is considered to be the primary thionic acid. The higher thionic acids are formed from trithionic acid by addition of sulphur, the chief sulphurising agent being thiosulphuric acid.

All the decompositions of thiosulphuric acid proceed with diminution of acidity. Formation of the anhydro-acid $\text{H}_2\text{S}_4\text{O}_5$ corresponds with the removal of about half the acidity, and to its formation is due the somewhat paradoxical result that thiosulphate is apparently much more stable in very strongly acid solution than in moderately acid solution. The acid $\text{H}_2\text{S}_4\text{O}_5$ has a strong reducing action on methylene-blue, indigo, etc., being itself oxidised to tetrathionate. The cause of the colour of certain simple inorganic sulphur compounds is considered and attributed to the presence of a sulphur atom with a ten-electron sheath.

The President, in commending the authors' courage in attacking one of the most heartbreaking problems in inorganic chemistry, suggested that the telluric acids presented an even greater problem.

Dr. R. H. Pickard remarked that many of the reactions mentioned are of importance in the manufacture of chrome leather. He also asked why pentathionic acid and not a higher thionic acid, was the terminal decomposition product.

Prof. Bassett replied that there were reasons for thinking that tetrathionic acid could have either of the structures I or II, and that addition of sulphur to the first produced pentathionic acid, III.

this building-up process is to be ascribed to the tendency of the sulphur atom to become co-ordinated with four other atoms or groups. Further attachment of sulphur to a compound of the above structure seems unlikely. A similar building-up of higher polythionates might, however, occur from the second form of tetrathionic acid, and this would lead finally to octathionic acid, IV, with hexa- and hepta-thionic acids as intermediate steps. Some experiments in progress suggested that this may actually be possible.

Dr. W. J. Hickinbottom presented the following paper:—

The constitution of the disaccharides. Part XIV. Melibiose and its relationship to raffinose. [With W. Charlton and W. N. Haworth.]

ZEMPLÉN (Ber., 1927, 60, 923) has advanced new constitutional formulæ for melibiose and raffinose differing from those which had previously been assigned to these sugars by Haworth. On the basis of Zemplén's formula, methylated melibiose should give rise on hydrolysis to tetramethylgalactose and to 2:4:6-trimethylglucose. Completely methylated melibiose leads on hydrolysis to the isolation of crystalline tetramethylgalactose and to 2:3:4-trimethylglucose. The latter sugar was converted to the crystalline 2:3:4-trimethyl- β -methylglucoside, identical with that isolated on previous occasions from methylated gentiobiose, methylated amygdalin, and methylated raffinose. Haworth's structural formula for melibiose is therefore substantiated by these results. In both melibiose and raffinose the galactose residue is attached to the glucose residue through position (6) in the glucose chain. Other evidence is communicated which shows that melibiose is probably not a β -bi-ose, and the suggestion is made (based on optical data) that the disaccharide is of the α -type.

Dr. R. H. Pickard, remarking that the chemical evidence appeared convincing, deprecated the employment of analogies invoking optical activity. He was suspicious of "rules" based on considerations of optical activity when advanced in support of views on constitution.

BIOCHEMICAL SOCIETY

A meeting was held on May 7 in the Physiology Department of the University of Manchester, when the following papers were read:—

"Variations in the serum calcium of rabbits," by Kathleen Culhane and S. W. F. Underhill.—With the object of discovering whether the rise in serum calcium following insulin injections, as described by Davies, Dickens and Dodds, was caused by the insulin itself or by some impurity associated with it, and of finding whether this would provide an explanation of the frequent erratic response of the animals to insulin, the effect of samples of varying degrees of purity has been studied. In most experiments 6 rabbits were given insulin and 4 controls received no insulin. No rise in serum calcium was obtained within a short period of time with samples of which the potency varied from 0.05 mg. to 8.0 mg. to the unit. The complete curves for 24 hrs. with 4-hourly injections of small doses

of insulin (0.5 unit per kg.) were then followed, both when the rabbits were fed with oats and hay alone and when they received cabbage also. An increase in the serum calcium occurred in both insulin-treated animals and controls only on feeding with cabbage. Cabbage may cause a rise in serum calcium, the effect depending on its previous level, in which seasonal variations play a part. There is no relationship between insulin convulsions and serum calcium.

"Experiments on the formation of succinic acid in the body," by P. W. Clutterbuck.—A polarimetric method for following the conversion of succinic to malic acid in liver and muscle pulp was described. Using the minced organs, rabbit liver was 8 times as active, weight for weight, as rabbit muscle in bringing about both the conversion of succinic to fumaric and fumaric to malic acid. Using the method, with the minced organs, no production of succinic acid from the following possible precursors could be detected:—acetone, sodium acetate, acetoacetate, α -ketoglutarate, δ -ketohexonate and diacetylsuccinate. Cyanide, whilst inhibiting completely the change from succinic to fumaric acid, has no action on the conversion of fumaric to malic acid. The latter change is, therefore, a simple addition of the elements of water and not an oxidation-reduction process.

"The action of tyrosinase on phenols," by C. E. M. Pugh and H. S. Raper.—Happold and Raper have shown that tyrosinase only deaminates amino acids in the presence of certain phenols. They suggested that the phenol is oxidised to its *ortho*-quinone, and that this in turn attacks the amino acid. The present work deals with the isolation of the *orthobenzoquinone* and *orthotoluquinone*, in the form of their anilino derivatives during the progress of the action of tyrosinase on phenol and *p*-cresol respectively. It is also shown that catechol and homocatechol give rise to *orthoquinones*. Peroxydase and hydrogen peroxide produce *o*-quinones from catechol and homocatechol. The *orthoquinones* are probably not the final products of the action of tyrosinase on phenols. Measurement of the oxygen absorption suggests that more highly oxidised substances are subsequently produced.

"Chemical changes in muscle," by E. Boyland and A. D. Ritchie.—The chemical changes in plain, cardiac and invertebrate muscle require carefully modified analytical methods. Glycogen, lower carbohydrates, lactic acid, inorganic phosphate and soluble organic phosphates, by means of a suitable scheme, can be estimated on one sample of 5 g. The alcohol-insoluble residue is used for glycogen estimation, using one quarter of the amount of caustic potash usually advised in Pflüger's method, and thus reducing the volume of liquid in which the glycogen is precipitated. The alcohol extract, when free from proteins and lipoids, is treated with copper sulphate and lime to precipitate hexoses. The filtrate can be used for lactic acid estimation except in the case of mollusc muscle containing taurine; the taurine must be removed by boiling with mercuric oxide. Lactic acid is estimated by steam distilling in presence of potassium permanganate in an apparatus fitted with ground joints. The avoidance of the presence of air in the oxidation reduces the over-

oxidation of acetaldehyde to acetic acid. Lobster muscle contains variable amounts of glycogen (0.05% to 0.20%), and this is converted quantitatively into *D*-lactic acid on standing in alkaline phosphate. The large adductor muscle of the pecten contains a large quantity of glycogen (2%) which is not converted into lactic acid under these circumstances.

"Fermentation of propionic acid by *Aspergillus Niger*," by P. D. Coppock and T. K. Walker.—When *Aspergillus Niger* is cultivated upon calcium propionate as sole source of carbon, the first detectable product of fermentation is lactic acid. Later pyruvic acid makes its appearance. In no instance has the production of the latter acid been noted prior to that of lactic acid, and no malonic acid is produced. This suggests that the pyruvic acid arises from the oxidation of the lactic acid, and this supposition has been confirmed by growing the mould upon calcium lactate solutions, when pyruvic acid was obtained. When the mould is grown upon calcium pyruvate, the following substances are produced: ethyl alcohol, glyoxylic acid, and oxalic acid. The probable course of the reaction is presumed to be: pyruvic acid \rightarrow acetaldehyde \rightarrow ethyl alcohol; acetic acid (dismutation), then acetic acid \rightarrow glycollic acid \rightarrow glyoxylic acid \rightarrow oxalic acid. This sequence is rendered likely by the observations that the fermentation of calcium acetate yields glycollic, glyoxylic and oxalic acids, and that glycollic acid on fermentation yields glyoxylic acid.

"The carbohydrate-phosphate component of animal nucleic acid," by J. Pryde and J. M. Peterson.—With the view of elucidating the nature of the carbohydrate component of animal nucleic acid, attempts are in progress to methylate sodium nucleate and the sugar-phosphate compound obtainable from it. For the purpose of isolating the latter the most promising results have been obtained by a method which involves the treatment of sodium nucleate with nitric acid in the cold, and is based on the results of Steudel. A syrupy product is obtained which contains organic phosphorus and reduces Fehling's solution. It is found to give marked pentose or glycuronic acid reactions with Bial's orcin reagent, and with Tollen's naphthoresorcinol reagent. The pigments obtained give definite absorption spectra similar to those of the corresponding pentose pigments, but not identical with those prepared from arabinose and rhamnose, or from glycuronic acid, with which they have been compared. The naphthoresorcinol pigment obtained both from the syrupy sugar-phosphate and from sodium nucleate directly, like those obtained from pentoses and unlike that obtained from glycuronic acid, is insoluble in ether. It is suggested that grounds exist for investigating in greater detail the possibility that the supposed hexose of animal nucleic acid may be a substituted pentose.

"Some observations on methylated glycerophosphates," by J. Pryde and E. T. Waters.—A preliminary study of methylated glycerophosphates is calculated to simplify the investigation of similar derivatives of the hexose phosphates of muscle. The dimethyl ester of dimethyl β -glycerophosphate is obtained by applying various methylation processes to sodium β -glycerophosphate. The phosphoric acid group is unaffected by

distillation in a high vacuum, and the pure ester is obtained as a very mobile syrup having n_D^{15} 1.4268. The barium and a crystalline brucine salt have been prepared. Mixed sodium and glycerophosphates have been synthesised by the action of trisodium phosphate on epichlorhydrin. The fractionation and methylation of these mixtures is being investigated with the view of obtaining a definite methylated monoglycero- α -monophosphoric acid. Sodium dimethyl β -glycerophosphate is not hydrolysed *in vitro* by kidney phosphatase, nor has any evidence of its hydrolysis *in vivo* been obtained when it is injected into the blood stream of anaesthetised dogs with ureteric cannulae. On the other hand, there is some evidence of a slow hydrolysis of the mixed methylated α -glycerophosphates by kidney phosphatase *in vitro*.

The following papers were also read: "The attempted isolation of a type precipitinogen from *B. aertrycke*," by F. C. Happold, and "Haemocyanin. Part IV. The dependence of the shape of the oxygen dissociation curve on the state of ionisation of the protein," by E. and E. Stedman.

SOCIETY OF PUBLIC ANALYSTS

An ordinary meeting was held at the Chemical Society's Rooms on May 4, Mr. E. Richards Bolton, President, being in the chair.

Certificates were read for the first time in favour of Messrs. C. E. Corfield, B.Sc., H. E. C. Powers, B.Sc., J. D. Rogers, and A. Samson, A.R.C.Sc.

Certificates were read for the second time in favour of Messrs. F. C. Bullock, B.Sc., T. H. Fairbrother, M.Sc., R. S. Rack, and S. G. Sherman.

The following were elected members of the Society:—A. G. J. Lipscomb, B.Sc., W. L. Matthews, S. J. Rogers, B.Sc., E. F. Waterhouse, H. W. Webb, A. S. Wood, M.Sc., Ph.D.

The following papers were read and discussed:—

"Investigations into the analytical chemistry of tantalum, niobium and their mineral associates. VII.—The precipitation of tungstic acid by tannin. VIII.—The separation of tungsten from tantalum and niobium" by Dr. W. R. Schoeller and C. Jahn.—Small quantities of tungstic acid are quantitatively recovered from tungsten solutions containing alkali chloride by precipitation with tannin and cinchonine hydrochloride. A method of determining small amounts of tungsten in the presence of large amounts of earth acids has been based on this principle. Small amounts of earth acids in tungstic trioxide are determined by fusing the mixture with sodium hydroxide and treating the fused mass with sodium chloride solution. Sodium tantalate and niobate remain undissolved.

"The separation of vanadium and tungsten," by S. G. Clarke, B.Sc.—Vanadium may be determined in the presence of large amounts of tungsten by precipitation with cupferron (ammonium salt of nitrosophenyl-hydroxylamine) after treatment of the solution with hydrofluoric acid, neutralisation with ammonia, addition of hydrochloric acid and dilution. The precipitate is separated, washed and ignited at a low temperature, the residual vanadium pentoxide dissolved in dilute

sulphuric acid, and the solution reduced with sulphur dioxide and titrated with permanganate.

“The determination of moisture by the volatile solvent method,” by J. M. Jones and T. McLachlan.—This method of determining moisture is satisfactory for emulsions, such as butter and margarine, and gives more consistent results than any other method for such products as jam, honey and malt extract, though it is not possible to say whether these results are accurate. For powders which do not cake, the water-oven and air-oven method is preferable to this method. The use of toluene as a solvent enables the results to be obtained in a shorter time than when benzene or petroleum spirit is used.

“A study of antimony trichloride as a possible quantitative reagent for vitamin A,” by F. Wokes, B.Sc., and Dr. S. G. Willmott.—The reaction between antimony trichloride and vitamin A is probably due to condensation, and can be retarded by dehydration of the solvent. The depth of the initial blue coloration obtained under standard conditions may be used to measure the vitamin A content of the oil. The intensity of colour is expressed in Lovibond blue units 30 seconds after mixing the solution of the oil and reagent.

New processes for the determination of certain elements in lead,” by Dr. B. S. Evans.—The sample is dissolved in nitric acid, lead separated as sulphate, and arsenic precipitated with sodium hypophosphite and separated by shaking with benzene and filtering. Antimony is determined in the filtrate, and the arsenic in the precipitate is determined by an iodimetric method. Bismuth is determined colorimetrically with potassium iodide after separation of the lead as sulphate and chloride, and sulphur is determined gravimetrically after dissolving the metal in *aqua regia*, evaporating the solution to dryness, and dissolving the residue in dilute hydrochloric acid.

CANADIAN INDUSTRIAL ACTIVITIES

The annual financial report of the Canadian General Electric Company, Ltd., for the year ending December 31, 1926, shows gross profits, after reserves and taxes have been deducted, but before providing for depreciation, amounting to \$1,870,618, which is \$253,525 above the 1925 figure, an increase of over 15%. The sum of \$700,000 has been written off for depreciation as compared with \$600,000 in 1925. Net profits are \$1,170,618, an increase of \$236,867, or over 25%, which is available for dividends and reserve. All outstanding interest-bearing charges have disappeared from the balance sheet.

The Dominion Rubber Co., Ltd., had sales amounting to \$19,708,040 in 1926, an increase of \$2,916,656, or 14 1/2%. The net income from operations, before interest and depreciation of plant were deducted, amounted to \$1,696,765. Interest on funded indebtedness and other interest charges left the net income at \$1,043,263. Depreciation of plant, \$490,155, and preferred dividends, \$210,000, left a net surplus for the year of \$343,108. The profits during the year were adversely affected by the decline in crude rubber prices during the early months of 1926, which forced drastic reduction in selling prices, especially of tyres made from high-priced rubber.

OBITUARY

DR. JAMES BURGESS READMAN

James Burgess Readman, D.Sc., F.R.S.E., died at Bradford-on-Avon on March 24. Dr. Readman was educated at Glasgow Academy, and his first engagement was with the firm of Townsend, of Glasgow, where he became familiar with the manufacture of various chemicals. He afterwards went to New Caledonia, to investigate the nickel deposits, and on his return to Scotland worked out a process for the extraction of nickel, and established a works to carry out the process. After a few years of successful operation, these works were taken over by a French company. For family reasons, Readman then went to live in Edinburgh, and there took a course of theoretical and practical chemistry with J. Falconer King, the City Analyst, and in the early eighties took the B.Sc. Degree at the University of Edinburgh. He then decided to establish a laboratory in Edinburgh, principally with a view to research and consulting practice. When at Townsends, he had been impressed with the wasteful and costly method of manufacturing phosphorus by the decomposition of calcium phosphate with sulphuric acid, and the subsequent reduction of the metaphosphoric acid with carbon in clay retorts, and had carried out experiments with the object of substituting silica for the sulphuric acid, and in one operation at a high temperature producing a fusible slag, and distilling off the phosphorus. Various types of furnace were tried and failed. During a visit with the British Association to Canada, he heard Cowles describe the electric furnace for the reduction of aluminium, and at once realised that this was the type of furnace to carry out the reaction. On his return to Scotland the experiments were continued, but great difficulty was experienced in obtaining a supply of current for the purpose, as at that time electric lighting was in its infancy. From laboratory to semi-manufacturing trials, one unit was erected, and the whole of the current from the Kelvinside Power Station, Glasgow, taken during the day time to prove on a working scale the feasibility of the process. Ultimately the patent rights were purchased by Albright & Wilson, Oldbury, and at the present time it is understood that all phosphorus is manufactured by the Readman process. Incidentally, it may be stated that he was the first to introduce the electric furnace into this country for manufacturing purposes.

Readman then turned his attention to another scheme which had occupied his mind for a time, viz., the manufacture of cyanide from atmospheric nitrogen. It was known that nitrogen, passed over barium carbonate in presence of carbon converted it into barium cyanide, but no practicable method of carrying out the reaction had been successful. By the application of a different type of electric furnace, it was demonstrated that the preparation of barium cyanide could be carried out continuously by a constant feed and discharge. The process was favourably reported on by Sir Wm. Ramsay and Sir Alex. Kennedy, after a series of trials on a large-scale plant, and works erected at Leven, Fife, but misfortune dogged the career of the company. About the time the works were ready the South African war broke out, and the demand for cyanide, the consumption

of which had been rapidly advancing, immediately dropped. Stocks accumulated in South Africa and in the factories, and the Scottish Cyanide Company was unable to market its product. Other difficulties arose, and ultimately the works had to be dismantled and the valuable electric plant sold. Many of his personal friends, as well as himself, lost money in the venture, and Readman never recovered from the effects of this failure. As a method of fixation of atmospheric nitrogen this method will, in the opinion of the writer, be again revived. Like many other inventors, Readman never received the pecuniary reward of his labours. Modest in demeanour, devoted to industrial science, he was a regular attender at the annual meetings of the Society of Chemical Industry of which he was an original member—and British Associations, and was intimate with the leading chemists of the time—Ramsay, Thorpe, Tilden, and others.

G. H. GEMMELL.

DR. G. WEYMAN

We deeply regret to announce the death, at the early age of 38, of Dr. Geoffrey Weyman, F.I.C., chief chemist to the Newcastle-upon-Tyne and Gateshead Gas Company. Dr. Weyman underwent a serious operation six weeks ago, but his condition subsequently became more grave, and he passed away on April 29.

Dr. Weyman was born at Guildford, Surrey, but came of an old Shropshire yeoman family. He was at school at Cheltenham, and later at the High School, Edinburgh, and when his father moved to Newcastle 22 years ago, he matriculated at Durham University twelve months before he could enter Armstrong College, filling up the intermediate time in his father's office.

Upon taking his degree, he became chemist to the Elswick Gas Works of the Newcastle & Gateshead Gas Co. It is interesting to note that he was the first trained chemist employed by the company, and gradually developed the scientific side of the business until he had quite a considerable staff under him. He was greatly encouraged in his work by Mr. Thos. Hardie, now engineer to the Gas Light & Coke Co.

He was held in high esteem for his scientific attainments, was a regular contributor to the Technical Press and the author of several technical books, including his well-known "Modern Gas-Works Chemistry." In the field of invention may be mentioned his patent "Rayflex" open fire coke-stoves, and his investigations on the properties of coke are now being appreciated. From time to time he contributed papers to the North of England Gas Managers Association, and took part in the discussions. He has been Chairman of the Auxiliary Section of the North of England Association, and was one of the founders of the Newcastle Chemical Industry Club, of which he was Hon. Librarian for several years.

Dr. Weyman had long been a member of committee of the local Section of the Society of Chemical Industry, and took a very active part in its meetings. In fact, his last public appearance was at the March meeting of this Section, when he took part in the discussion, although obviously in ill-health.

Married in June, 1914, on the outbreak of the War, he was called up as an O.T.C., in due time going to the front,

but after some months was sent home for munition work.

Of a reserved and quiet nature, he yet commanded the complete devotion and loyalty of those under him. Sincere sympathy in their bereavement will be felt with his widow and three children. The interment was on May 2, in Lamesley Cemetery.

CORRESPONDENCE

THE STATUS OF SCIENTIFIC WORKERS

SIR,—My attention has been drawn to the letter from Mr. Bertram Ward which appeared in your issue of April 29, referring to the appeal which has been circulated by the above society.

Apparently Mr. Ward is in full sympathy with the main object of the appeal, that is to build up a body comprehending scientific workers in every branch of science, pure and applied, and in every kind of professional scientific occupation, in order to educate the general public towards a greater appreciation of the function of science in the national life, and thus create a greater demand for the services of scientific workers. But if I interpret him correctly, he is against collective bargaining with employing authorities for the purpose of obtaining better salaries and conditions of service for the members of a profession. The individual scientific worker is to be left unrestricted to make his own terms with employers backed up by reasoned yet vigorously insistent propaganda of a general character. Such a method he suggests is irresistible.

It would be interesting to know what Mr. Ward would include in the term "propaganda." Let me give one example: A few months ago the Air Ministry advertised for a scientist of specific qualifications and experience for a post of some responsibility. The salary attached to the post was, in the opinion of my Executive, quite inadequate. Accordingly they asked the Institute of Chemistry to join them in a deputation to the Air Ministry. As a result of the representations made by this deputation, the initial salary attached to the post was appreciably increased. Would Mr. Ward call this collective bargaining or educative propaganda? Would he suggest that this method was beneath the dignity of the representatives of the two bodies? Instances of this kind could be multiplied. It is notorious that the British Medical Association has successfully boycotted certain local authorities which have offered inadequate salaries to qualified medical practitioners; that this Association definitely recommends its members not to apply for such posts. Does Mr. Ward include such action under the heading of propaganda? Other professional bodies also lay down definite minimum scales of charges or minimum salaries for their members, and enforce them by characterising those who accept less than the minimum laid down as guilty of unprofessional conduct. This could hardly be called collective bargaining, and it would be difficult to see how it could be called propaganda, but it has certainly proved effective in raising the members of these professions in the public esteem.

Mr. Ward should consider this fact. If the present inordinately low salaries continue to be offered to men of high qualifications and experience in the various scientific

occupations, the standard of entry of the profession will be lowered. Let me draw his attention to a passage from the Report of the Medical Research Committee for the year 1925 to 1926 (p. 12):—"the Council have pointed to the urgent need for an improvement in the rewards and conditions of work and for an advance in public recognition of its value, intellectual and material, without which the recruitment of the best brains to this high type of national service is not likely to be effectively secured." They continue by stating that there are many urgent problems now waiting for solution, for which solution is confidently to be expected by methods already within reach, but "is delayed by a shortage of the most competent men."

Yours faithfully,

A. G. CHURCH, *General Secretary*,
National Union of Scientific Workers

PERSONAL AND OTHER ITEMS

Mr. T. R. Ferens, joint chairman of Rickett & Sons, Ltd., a generous benefactor to Hull, celebrated his 80th birthday on May 4. It will be remembered that Mr. Ferens gave £250,000 for the establishment of a university college at Hull.

Mr. S. G. M. Ure, M.A., M.I.Chem.E., has been appointed Hon. Editor of the Proceedings of the Chemical Engineering Group.

We regret to learn of the death, at the age of 66, of Prof. Adolf Miethe, one of the foremost authorities on photographic chemistry. In 1924 Prof. Miethe announced that he had obtained gold from mercury, but the claim is not yet generally accepted.

The death is announced from New York of Mr. Hudson Maxim, a well-known expert on explosives.

The following deaths are announced from Germany:—Dr. A. Liebmam; Prof. K. Windisch, professor of chemistry and agricultural technology at Hohenheim; Dr. R. Meyer, who was the first to elucidate the constitution of fluorescein; Dr. A. Ganswindt, formerly editor of the *Deutschen Farbenzeitung*.

The late Mr. J. E. C. Lord, managing director of J. E. C. Lord (Manchester), Ltd., tar distillers and manufacturing chemists, left £127,441.

Standardisation of Tar Products Tests Committee

As a result of the Tar Conference held in Manchester during November last year, the Joint Committee of the Institution of Gas Engineers, the Coke Oven Managers' Association and the Fuel Section of the Society of Chemical Industry has appointed a Standardisation

Tar Products Tests Committee consisting of the following gentlemen:—Mr. W. G. Adam, of the Gas Light & Coke Co.; Mr. S. Billbrough, of the Yorkshire Tar Distillers, Ltd.; Mr. G. B. Brook, of the British Aluminium Co., Ltd.; Dr. T. Howard Butler, of Wm. Butler & Co. (Bristol), Ltd.; Dr. A. F. Campbell, of Hardman & Holden, Ltd.; Mr. W. T. Collis, of the M. I. Land Tar Distillers, Ltd.; Dr. H. G. Coleman; Mr. E. V. Evans, of the South Metropolitan Gas Co.; Mr. H. Fergusson, of Burt, Boulton & Haywood, Ltd.; Mr. C. P. Finn, of the Coke Oven Managers' Association; Mr. A. G. Francis, of the Government Laboratory; Mr. G. A. Hebden, of the South Yorkshire Chemical

Works, Ltd.; Mr. H. W. James, of the South Metropolitan Gas Co.; Mr. J. H. B. Jenkins, of the London & North Eastern Railway; Mr. J. MacLeod, of the Glasgow Corporation Chemical Works Department; Mr. J. P. Miller, of John Miller & Co. (Aberdeen), Ltd.; Mr. H. E. Nickels; Mr. T. F. E. Rhead, of the City of Birmingham Gas Department; Dr. J. A. Roelofsen, of Dorman, Long & Co., Ltd.; Mr. F. S. Sinnatt, of the Fuel Research Board; Dr. P. E. Spielmann; Mr. G. E. Thomas, of the Graigola Merthyr Co., Ltd.; and Mr. W. J. U. Woolcock, C.B.E., of the Association of British Chemical Manufacturers.

Mr. Woolcock was asked to take, and accepted, the Chairmanship of the Committee. Dr. E. W. Smith and Mr. R. M. Drake were appointed Honorary Secretary and Assistant Honorary Secretary respectively.

The above General Committee, at its first meeting on April 12, appointed panels to deal with the standardisation of methods of testing tar and tar products as classified below:—

A.—Crude Tar.

B.—Pitch, Refined Tar and Creosote.

C.—Benzole Group of Substances and Pyridine.

D.—Carbolic Compounds; Naphthalene; Anthracene, etc.

and further panels to deal with:—

X.—Apparatus, Constants, etc.; and

Y.—Editorial (to obtain uniformity in terms and units throughout standard tests).

These panels will report back to the General Committee on the work they undertake, and throughout their investigations will work in close collaboration with the British Engineering Standards Association, the American Society for Testing Materials, the Institution of Petroleum Technologists, and other competent bodies.

All communications should be addressed to the Honorary Secretary, at 166, Piccadilly, London, W.1.

Reported Negotiations between British and German Chemical Industries

According to the *Financial Times*, a statement from Berlin indicates that a comprehensive agreement between German and British chemical industries is impending. The consummation of such an agreement would give the combination control of 37% of the total world export of chemicals and two-thirds of the world's dye production. The British United Press has learned at the headquarters of the German Dyestuffs Trust that the negotiations are proceeding satisfactorily. It is stated authoritatively that the agreement which is envisaged would provide for the exchange of German dye patents and information on manufacturing procedure, in return for a share (estimated at 50%, a figure which is not confirmed) in the British and Colonial dyestuffs markets. It is thought that the arrangement between Britain and Germany will not be limited to dyestuffs, but will include an arrangement for the manufacture and sale of mixed fertilisers, artificial silk, oil extracted from coal, and photographic, pharmaceutical and other chemicals.

Sir Alfred Mond, chairman of Imperial Chemical Industries, Ltd., accompanied by Sir Harry McGowan, chairman and managing director of Nobel Industries,

Ltd., was the guest last week of Dr. Carl Duisberg, President of the German Federation of Industries, at his estate at Leverkusen, adjoining the dyestuffs works. The British visitors later inspected the chemical works at Oppau and Leuna, after which German dyestuff shares are said to have risen greatly in value.

It is taken as a significant fact that Brunner, Mond and Co., Vickers, and the United Steel Companies are interested with the Shell Company in operating German patents for the hydrogenation of coal. Furthermore, Nobel Industries, Ltd., a constituent of Imperial Chemical Industries, Ltd., owns 7,500,000 marks worth (about £370,000) of shares in the German Koeln Rottweil Explosives Company, which last year merged with the German Dyestuffs combine. Courtaulds, the artificial silk firm, is interested with the German Dye Trust in the production of artificial silk. Moreover, the German Dye Trust is reported to be connected with the Anglo-Persian Oil Company. Other special chemical agreements between Germany and Britain are said to involve creosote oil, borax and benzol.

Errata

In the issue of May 6, on p. 409, col. 1, line 27, after the words "vitamins and," insert "hormones"; on p. 409, col. 2, line 5, for "incision," read "excision."

REVIEW

ARTIFICIAL FERTILISERS, THEIR CHEMISTRY, MANUFACTURE AND APPLICATION. By P. PARRISH, A.I.C., M.I.Chem. E., and A. OGILVIE, A.M.I.Mech.E., with a foreword by Dr. H. C. Brown. Vol. I. Pp. 355. London: Ernest Benn, Ltd., 1927. Price 45s. net.

Any technical work with which Mr. Parrish's name is associated is sure to be read by all interested in the technology of the subject, and the foreword by Dr. H. C. Brown will secure for the present work the interest of all connected with the British fertiliser trade. One cannot, however, refrain from supporting Dr. Brown when he says that he cannot agree with all the views expressed or all the data furnished, but in a work of this kind, which covers so large a field in great detail, there is bound to be a certain amount of debatable matter. Moreover, if this were not so, the book would not fulfil the purpose for which it has been written: that of indicating the problems with which the industry is faced to-day, and stimulating the examination of new ideas and new methods.

Quite half of "Artificial Fertilisers" is devoted to the history, chemistry and manufacture of superphosphate: compound manures and basic slag being also dealt with. The authors inform us in their preface that a second volume is to be published, which will, no doubt, describe the manufacture of nitrogen and potash fertilisers, which are only dealt with in the present work in their connexion with compound manures.

Mr. Parrish and Mr. Ogilvie are to be congratulated on having compiled a complete and up-to-date book of reference for the superphosphate industry, and although some of the figures relating to output and efficiency of machinery are perhaps open to question, there is no doubt that the work will prove a very useful one.

It is suggested that manufacturers of superphosphate have, in the past, paid more attention to the mechanical

condition of their product than to its chemical properties, but those who understand the difficulty of obtaining the maximum of soluble phosphate which is compatible with fine condition for mechanical distribution will not be surprised at this.

The world's output of phosphate rock, with full statistics, and a description of the mining processes employed, the manufacture, storage and despatch of superphosphate, compound fertilisers and basic slag are all dealt with in very complete detail.

The chapters dealing with mechanical den excavators, grinding mills, mixing, screening and bagging machines are very thorough; describing the practices and machines in vogue in European and American works, and comparing their output and efficiency in the fullest manner.

The depressed condition of the British superphosphate trade is commented on and discussed, the suggestion being made that British Nauru phosphate should be supplied to British manufacturers of superphosphate, less interest and sinking fund charges, for a period sufficiently long to enable the industry to recover from the effect of competition arising from depreciated foreign exchanges. Whether the deduction of these charges would enable Nauru phosphate to be delivered in this country at a price sufficiently low to compete with the very low price of North African phosphate is doubtful, but, in any event, the suggestion is not a new one, having been considered by more than one postwar Government and rejected after careful consideration.

The last chapter is devoted to the consideration of the trend of future developments in the direction of finding other methods of rendering phosphate soluble in water, and, after surveying the various attempts which are being made to this end, the authors conclude by advising the superphosphate manufacturers to watch all new processes.

As stated above, this work is a very useful one, and should be read by all fertiliser manufacturers.

COMPANY NEWS

NOBEL INDUSTRIES, LTD.

A further dividend has been declared on the ordinary shares of 12% less tax, making 15% for the year, and also a dividend has been announced on the deferred shares of 10% less tax.

ASSOCIATED LEAD MANUFACTURERS, LTD.

The profit for 1926 amounted to £65,079, compared with £132,071 for 1925. Interest on secured notes absorbed £9484, and the preference dividend absorbed £46,238. The directors propose to write off the preliminary expenses £8974. No dividend is recommended on the ordinary capital of £1,448,409, the balance of £50,213 being carried forward, against £49,831 brought in.

BRITISH CYANIDES CO., LTD.

This company is now offering 672,838 ordinary shares of 2s. each to existing holders in the proportion of two new shares for each ordinary held on April 25. The directors report a marked improvement in the position of the company since Christmas. In March there was a profit of £92, against a loss of £418 in February and a loss of £845 in January. The improvement in the price of prussiate of soda has been maintained, and new markets are being found for thiocarbamide and other

chemicals, the sale of which leaves a satisfactory margin of profit. All profits derived from the new synthetic resin or any products made therefrom are shared equally by the company with the Beetle Products Company. The consumption of moulding powders continues to expand. The cotton process has been the subject of intensive research work by the Bleachers' Association in collaboration with the Bradford Dyers' Association and the company, with the result that the Bleachers' Association has erected plant for operations on a semi-commercial scale.

BRITISH OIL AND CAKE MILLS, LTD.

The twenty-ninth ordinary general meeting was held on April 12, Mr. J. W. Pearson, chairman, presiding. In order to establish the brand "New-Pin" soap, a very heavy expenditure on advertising had been made. The directors had now decided to abandon this scheme, and the advertising expenditure had been written off, so that the year 1927 had been started free from encumbrances. Many mills in this industry had to close down owing to the coal strike, whilst others, including most of those belonging to the company, carried on by using oil fuel in place of coal. This was more expensive, and it was estimated that the cost of seed crushing during the last six months of 1926 cost £150,000 more than for the first six months of the year. The importation of oilseeds during 1926 was 255,000 tons less than in 1925, while, as compared with the same period there was an increase in the importation of foreign-made cakes of 40,000 tons and of oils 38,000 tons. There were indications of improvement in general conditions for 1927. Whilst the trading results of 1926 were better than 1925, a further betterment of the position was anticipated at the end of the current year.

UNITED GLASS BOTTLE MANUFACTURERS, LTD.

The fourteenth ordinary general meeting, held on April 21, was presided over by Mr. G. E. Alexander, who had been elected chairman in succession to the late Sir Ernest F. Oldham. Sir Max J. Bonn, K.B.E., and Major W. F. Dixon-Nuttall, D.S.O., had joined the board, the former being elected deputy-chairman. During the year work was commenced on the extensive improvements in plant and equipment to which the directors had given long and careful consideration, and over £82,000 was expended on capital account, principally at the St. Helens factories. Owing to the general strike and the coal strike, the trading profit of the company and its subsidiaries did not come up to expectations. The reduction in operating capacity in the factories utilising coal amounted to between 40 and 50%, meaning a loss in output of over 50,000,000 bottles, whilst the operation of the remaining furnaces necessitated the purchase of over 30,000 tons of coal at ruinous prices in order to meet the most urgent demands of customers. The first fiscal period of the year shows results which compare more than favourably with the corresponding period of 1926. Competition from home and foreign manufacturers was still very keen, but the Board were confident that the policy of concentration and modernisation of existing plants, together with the consistent quality and service of the company, would enable them to maintain their position as the premier glass bottle manufacturers of this country.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4 ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Sal ammoniac.—£45—£50 per ton. Chloride of ammonia £37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate.—2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, oaks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb., according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic, Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
Lamp Black.—£35 per ton, barrels free.
Lead Hyposulphite.—9d. per lb.
Lithophone, 30%.—£22 10s. per ton.
Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
Sulphur Chloride.—4d.—7d. per lb., carboys extra.
Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
Vermilion, pale or deep.—6s.—6s. 3d. per lb.
Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
Red Liquor.—9d.—1s. 16° Tw. per gal.
Wood Creosote.—1s. 9d. per gal., unrefined.
Wood Naphtha.—Miscible, 4s.—4s. 3d. per gal., 60% O.P. Solvent, 4s. 3d. per gal., 40% O.P.
Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
Brown Sugar of Lead.—£40 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8½d.—9d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.
Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. Steady. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 8d.—2s. 3d. per gal., ex works in tank wagons.
Toluole.—90%, 1s. 9d. to 2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
Xylol.—2s.—2s. 4d. per gal. Pure, 3s. per gal.
Creosote.—Cresylic 20/24%, 10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/100, 1s. 10d.—1s. 11d. per gal. Solvent 95/100, 1s. 6d.—1s. 7d. per gal. Solvent 90/190,—1s. 1½d.—1s. 4d. per gal.
Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
Naphthalene.—Crystals,—£11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
Pyridine.—90/140.—8s. 6d.—13s. per gal. Nominal. 90/180—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
Acid Gamma.—4s. 9d. per lb.
Acid Amidonaphthol disulpho (1.8.2.4).—10s. 0d. per lb.
Acid H.—3s. 3d. per lb. 100% basis d/d.
Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
Acid Neville and Winther.—4s. 9d. per lb. 100% basis. d/d.
Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.
Aniline Salts.—7d. per lb., naked at works.
Anthranilic Acid.—6s. per lb. 100%.
Benzaldehyde.—2s. 3d. per lb.
Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
Benzoic Acid.—1s. 8½d. per lb.
o-Cresol 29/31° C.—4d. per lb.
m-Cresol 98/100%.—2s. 8½d. per lb.
p-Cresol 32/34° C.—2s. 8½d. per lb.
Dichloraniline.—2s. 3d. per lb.
Dimethylaniline.—2s. per lb. d/d. Drums extra.
Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
Dinitrochlorbenzene.—£84 per ton d/d.
Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
Diphenylamine.—2s. 10d. per lb. d/d.
α-Naphthol.—2s. per lb. d/d.
β-Naphthol.—11d.—1s. per lb. d/d.
α-Naphthylamine.—1s. 3d. per lb. d/d.
β-Naphthylamine.—3s. per lb. d/d.
p-Nitraniline.—1s. 9d. per lb. d/d.
m-Nitraniline.—3s. per lb. d/d.
o-Nitraniline.—5s. 9d. per lb.
Nitrobenzene.—6d. per lb., naked at works.
Nitronaphthalene.—1s. 3d. per lb. d/d.
R. Salt.—2s. 2d. per lb. 100% basis d/d.
Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
o-Toluidine.—8d. per lb., naked at works.
p-Toluidine.—2s. 2d. per lb. ex works, naked.
m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Purc, 80%.—£39 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb. Firm and Disk.
Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s. 3d. per oz.; 500 oz. lots—1s. per oz.
Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
Acid, Camphoric.—19s.—21s. per lb.
Acid, Citric.—1s. 5½d.—1s. 7d. per lb. Less 5%. Advancing.
Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
Acid, Salicylic.—B.P. 1s. 3½d.—1s. 4d. per lb. Technical 11½d.—1s. per lb. Both in good demand.
Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
Acid, Tartaric.—1s. 3d. per lb. Less 5%. Firm market.
Amidol.—9s. per lb. d/d.
Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
Amidopyrin.—8s. 6d. per lb.
Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
Atropine Sulphate.—11s. per oz. for English make.
Barbitone.—6s. 6d. per lb.
Benzonaphthol.—3s. 3d. per lb.
Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuth B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 4d.—2s. 5d. per lb. Potassium.—1s. 11d.—2s. per lb. Sodium.—2s. 2d.—2s. 3d. per lb. All spot.

Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Cresote Carbonate.—6s. per lb.

Ether meth.—1s. 1d.—1s. 1½d. per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Gaiacol Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb., for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron. Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—22s. per cwt., 112 lb. lots.

Magnesium Carbonate.—Light Commercial £33 per ton net.

Magnesium Oxide.—Light Commercial £67 10s. per ton, less 2½%; Heavy Commercial £22 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 10s. 6d.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig. 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonol.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—3s. per lb.

Phenazone.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar) 97s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 5d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Resorcin.—4s. per lb. spot.

Saccharin.—55s. per lb. Very limited enquiry.

Solol.—2s. 4d. per lb.

Sol. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sol. Citrate, B.P.C., 1911.—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sol. Ferrocyanide.—4d. per lb., carr. paid.

Sol. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sol. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonol.—7s. 6d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.

Thymol, Puriss.—11s.—12s. per lb., according to quantity. Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (*ex Anethole*).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. 6d. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 3d. per lb.

Ethyl Cinnamate.—10s. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—27s. 6d. per lb. Safrinol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—13s. per lb.

Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure—6s. per lb.

Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 9d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 16s. 9d. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The Complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 2nd. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on May 19th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Baker. Heat-exchangers. 11,123. Apr. 26.
British Dyestuffs Corp., Ltd., and Chapman. Preparation of foams for fire extinction. 11,020. Apr. 25.
Broadbent & Sons, Ltd., and Hallitt. Centrifugal driers. 11,552. Apr. 30.
Brunler. Evaporating apparatus. 11,000. Apr. 25.

Erzröstung Ges., and Balz. Mechanical kilns. 11,015. Apr. 25.

L.-G. Farbenind. Producing solid materials in state of fine dispersion. 11,050. Apr. 25. (Ger., 28.4.26.)

Kocour. Apparatus for determining strength of solutions. 11,600. Apr. 30. (U.S., 1.5.26.)

Marsden, and Meldrums, Ltd. Apparatus for effecting intimate contact of gases and liquids. 11,308. Apr. 28.

Reavell. Spray drying-apparatus. 11,270. Apr. 27.

Salerni. Treatment of gases etc. 11,192 and 11,197. Apr. 26.

Thiesen. Apparatus for treating gases with liquids. 11,607. Apr. 30. (Ger., 3.5.26.)

Whitnough. Apparatus for production of dispersions of solids in liquids. 11,414. Apr. 29.

I.—Complete Specifications

7562 (1926). Carrier Engineering Co., Ltd., and Groom. Drying and separation from gases of soluble and condensable vapours, and impurities. (269,714.)

18,327 (1926). L.-G. Farbenind. Manufacture of nickel catalyst. (255,884.)

22,355 (1926). General Rubber Co. Furnaces for supplying drying-gases. (267,464.)

24,553 (1926). Visco Engineering Co., Ltd., and Smith. Apparatus for treating air or gas with liquid. (269,790.)

26,267 (1926). Kropp. Settling-tanks. (260,279.)

31,478 (1926). Babcock & Wilcox, Ltd (Babcock & Wilcox Co.). Utilising the heat of materials discharged from furnaces and kilns. (269,813.)

*26,781 (1926). Caals. Filter cloths. (269,841.)

*8982 (1927). Andveo Corp. Fire-extinguishing composition. (269,879.)

*9349 (1927). Akt. Separator. Centrifugal separator installations. (269,883.)

*10,034 (1927). Boyner and Pehrson. Introduction of air or gaseous fluid into the charge in rotary furnaces. (269,892.)

II.—Applications

Dubbs. Cracking hydrocarbon oils. 11,461. Apr. 29.

Dvorkovitz. Manufacture of carburetted water-gas. 11,272. Apr. 27.

Holzappel. Protecting interior of oil cracking retorts etc. 11,005. Apr. 30.

L.-G. Farbenind. Conversion of hydrocarbons. 11,347—8. Apr. 28. (Ger., 1.5.26.) Conversion of coaly materials into liquid products. 11,569. Apr. 30. (Ger., 5.5.26.)

Lederer. Apparatus for producing gas. 11,378. Apr. 28. (Austria 28.4.26.)

Lee and Thompson. Gas tar filter extractor. 11,297. Apr. 28.

Low Temperature Carbonisation, Ltd., and Parker. Distillation retorts. 11,295. Apr. 27.

Meyer. Fuels for internal-combustion engines etc. 11,612. Apr. 30.

Pollock. Cracking hydrocarbon oil. 11,462. Apr. 29.

Salerni. 11,192 and 11,197. See I.

Toula. 11,065. See III.

White (Illinois Anthracite Corp.). Apparatus for producing smokeless etc. fuel. 11,175. Apr. 26.

II.—Complete Specifications

25,082 (1925). Jackson (Western Gas Construction Co.). Manufacture of water-gas. (269,221.)

1681 (1926). Weber. Production of coke briquettes. (269,655.)

2287 (1926). Bentley and Appleby. Gas producers. (269,689.)

2561 (1926). Patart. See XX.

7295 (1926). Wannebo. Manufacture of gas from oil or tar or cracking oil or tar. (269,711.)

*448 (1927). Aluminum Co. of America. Calcining of coke. (269,849.)

*10,865 (1927). Soc. des Prod. Chim. de Clamecy. Distillation of wood. (269,927.)

III.—Application

Toula. Treatment of oils, tars, etc. 11,065. Apr. 25.

III.—Complete Specification

7295 (1926). Wannebo. See II.

IV.—Applications

British Dyestuffs Corp., Ltd., Bunbury, and Shepherdson. Manufacture etc. of aroylating agents. 11,146. Apr. 26.

British Dyestuffs Corp., Ltd., Baddiley, and Chorley. Dyes. 11,372. Apr. 28.

Carpmael (L.-G. Farbenind.). Manufacture of azo dyestuffs. 11,179. Apr. 26.

Dehn (Newport Co.). Making N-dihydro-1,2,2,1-anthraquinone azine. 11,017. Apr. 25.

L.-G. Farbenind. Production of orange vat dyestuffs. 11,052. (Ger., 15.11.26.) Manufacture of mordant dyestuffs. 11,288. Apr. 27. (Ger., 27.4.26.)

Imray (L.-G. Farbenind.). 11,187. See XX.

IV.—Complete Specifications

8762 (1926). L.-G. Farbenind. See XX.

*10,819 (1927). L.-G. Farbenind. Manufacture of dye stuffs. (269,918.)

V.—Applications

Carpmael (L.-G. Farbenind.). Dressing artificial silk. 11,178. Apr. 26.

L.-G. Farbenind. Treatment of fibrous materials etc. 11,567. Apr. 30. (Ger., 21.1.25.)

Laucks. Cellulose fibre product. 11,589. Apr. 30 (U.S., 3.5.26.)

Muller. Manufacture of cellulosic materials 11,048. Apr. 25.

Nanji. Treatment of plant materials etc. 11,410. Apr. 29.

Pathé Cinema Anciens Etablissements Pathe Frères. Mixtures of organic substances which can be adsorbed by cellulose ethers etc. 11,494. Apr. 29. (Fr., 13.4.27.)

Wells. Cooking vegetable fibre. 10,998. Apr. 25. (U.S., 29.6.26.)

V.—Complete Specifications

25,468 (1925). Mount. Wood pulp production. (269,256.)

28,282 (1925). Clavel. Treatment of products or goods of or containing cellulose acetate. (269,605.)

29,487 (1926). Heberlein & Co. Chemically varying artificial silk. (261,792.)

*10,704 (1927). Barbou and Delvaile. Treating residual liquors from treatment of cellulose material. (269,909.)

VI.—Applications

Bunney. 11,089. See XIII.

L.-G. Farbenind. Manufacture of wetting-agents. 11,061. Apr. 25. (Ger., 23.4.26.) Dyeing. 11,287. Apr. 27. (Ger., 27.4.26.) Dyeing. 11,499. Apr. 29. (Ger., 29.4.26.)

VI.—Complete Specifications

*10,818 (1927). Chem. Fabr. Milch, and Lindner. Dyeing or printing with mordant dyestuffs. (269,917.)

*10,952 (1927). L.-G. Farbenind. Dyeing and printing cellulose esters and ethers. (269,934.)

*11,061 (1927). L.-G. Farbenind. Manufacture of wetting agents. (269,942.)

VII.—Applications

Ashcroft. Extracting alumina, potash, lime, etc. from silicates. 11,350. Apr. 28.

British Dyestuffs Corp., Ltd., Payman, and Piggott. Removal of free chlorine acid bromine from fluid mixtures 11,256. Apr. 27.

Craig, Kirkham, and Spence & Sons. Treatment of siliceous materials. 11,309. Apr. 28. Preparation of silica from silicate solutions. 11,310. Apr. 28.

Gaillard. 11,384. See XVI.

Johnson (L.-G. Farbenind.). Production of alkali metal nitrates. 11,051 and 11,482. Apr. 25 and 29.

Liljenroth. Treating material containing magnesium. 11,138. Apr. 26. (Sweden, 15.1.27.)

Liljenroth. 11,007 and 11,096. See XVI.

Metallwerk Plansee Ges. Production of molybdic and tungstic acid. 11,157. Apr. 26. (Ger., 26.4.26.)

VII.—Complete Specifications

782 (1926). Johnson (L.-G. Farbenind.). Manufacture of iron carbonyl. (269,625.)

1771 (1926). Simonis, and Liquid Air, Ltd. Liquid air oxygen-producing plant. (269,661.)

13,997 (1926). Uhde. Synthetic production of ammonia. (253,122.)

18,972 (1926). West Virginia Pulp & Paper Co. Converting alkali sulphides into alkali sulphites. (260,552.)

20,784 (1926). Stevens, Norris, and Watson. Purification of zinc sulphate solutions preparatory to electrolysis. (269,776.)

20,787 (1926). Stevens, Norris, and Watson. Removal of phosphorus from metal-bearing solutions. (269,778.)

20,788 - 9 (1926). Stevens, Norris, and Watson. See X.

*8943 (1927). Metallbank u. Metallurgische Ges. Treating lithium-containing silicates. (269,878.)

*10,669 (1927). Urbain Corp. Recovery of phosphorus and hydrogenated compounds thereof. (269,908.)

*10,827 (1927). Gaillard. See XVI.

*11,157 (1927). Metallwerk Plansee Ges. Production of molybdic and tungstic acid. (269,947.)

VIII.—Application

Quartz et Silice. Drawing silica glass etc. 11,455. Apr. 29. (Fri., 4.5.26.)

VIII.—Complete Specifications

25,951 (1925). Webster. Kilns for burning clay products etc. (269,344.)

837 (1927). Soc. Anon. des Manuf. des Glaces et Prod. Chim. de St.-Gobain, Chauny, & Cirey. Glass. (264,495.)

IX. Applications

Aerocrete (Foreign), Ltd., and Nicol. Production of porous concrete etc. 11,356. Apr. 28.

Iwanowski and Turski. Impregnation of wood etc. 11,382. Apr. 28.

X.—Applications

Cunningham and Huggins. Treatment of tin-bearing materials. 11,277. Apr. 27.

Drums, Ltd., and Jessop. Cleaning metal surfaces. 11,527. Apr. 30.

Garnett, Holden, and Smith. Refining nickel alloys etc. 11,075. Apr. 25. Magnetic alloys. 11,584. Apr. 30.

Guggenheim Bros., Macgowan, and Smith. Flotation processes. 11,441. 11,445. 11,448. 11,464. Apr. 29. (U.S., 3.8.26 and 24.1.27.)

Parker Rust Proof Co. Rust proofing etc. 11,035 - 6. Apr. 25. (U.S., 10.5.26.)

Rey. Ferrous metals. 11,172. Apr. 26. (Fr. 27.4.26.)

Smith. Treatment of ores containing platinum. 11,184. Apr. 26.

X—Complete Specifications

2033 (1926). Johnson (L.-G. Farbenind.). Manufacture of pure iron. (269,677.)

19,697 (1926). Tottman. Solder for aluminium and aluminium alloys. (269,771.)

20,786 (1926). Stevens, Norris, and Watson. Acid extraction of metals such as zinc and vanadium. (269,777.)

20,788—9 (1926). Stevens, Norris, and Watson. Recovery of vanadium solutions. (269,779—80.)

22,178 (1926). Electrolytic Zinc Co. of Australasia. Treatment of zinc ores for recovery of zinc by electrolytic deposition. (258,575.)

*6882 (1927). Jessup. Preparation of magnesium and alkaline-earth metals. (269,864.)

XI.—Applications

Electric Furnace Co., Ltd. (Northrup). Electric induction furnaces. 11,162—3. Apr. 26.

Tainton. Electrolysis. 11,490. Apr. 29.

Zimmermann. Production of insulating materials. 11,353. Apr. 28.

XI.—Complete Specifications

26,081 (1925). Cellino. Electrical cell. (241,898.)

1041 (1926). Harrison and Campbell. Electric batteries. (269,633.)

14,078 (1926). Pfanhauser, and Langbein-Pfanhauser-Werke. Galvanic baths. (269,753.)

20,784 (1926). Stevens, Norris, and Watson. See VII.

22,178 (1926). Electrolytic Zinc Co. of Australasia. See X.

XII.—Applications

James. Manufacture of soap. 11,465. Apr. 29.

Tillisch. Vitaminising fats. 11,114. Apr. 26. (Ger., 28.4.26.)

XII.—Complete Specification

*8082 (1927). Anc. Etab. Pellerin. Apparatus for melting fatty substances. (269,873.)

XIII.—Applications

Alcock. Manufacture of white pigment. 11,286. Apr. 27. Bunnay. Waterproofing etc. composition. 11,080. Apr. 26.

Coles. Producing white lead. 11,313. Apr. 28.

Johnson (L.-G. Farbenind.). Production of cellulose ester resin lacquers. 11,480. Apr. 29. Production of coloured coating-lacquers. 11,481. Apr. 29.

Laporte, Ltd., and Weber. Manufacture of white pigment. 11,286. Apr. 27.

XIII.—Complete Specification

235 (1926). Imray (Soc. Chem. Ind. in Basle). See XX.

XIV.—Application

Head. Treatment of rubber latex. 11,526. Apr. 30.

XIV.—Complete Specifications

2498 (1926). Stevens. Manufacture of vulcanite. (269,693.)

13,159 (1926). Porritt, Dawson, and Research Assoc. of British Rubber and Tyre Manuf. Preservation of goods of rubber etc. (269,745.)

XV.—Complete Specifications

16,716 (1926). Manfred. Production of artificial horn. (269,761.)

17,164 (1926). L.-G. Farbenind. Manufacture of chromium-magnesium preparations suitable for tanning. (255,087.)

19,912 (1926). Mathieson Alkali Works. Tanning-processes. (256,979.)

XVI.—Applications

Gaillard. Obtaining superphosphates. 11,384. Apr. 28. (Spain, 25.10.26.)

Liljenroth. Treating raw phosphate etc. 11,007 and 11,096. Apr. 25 and 26. (Sweden, 31.12.26 and 8.1.27.)

XVI.—Complete Specification

*10,827 (1927). Gaillard. Increasing the richness of superphosphates. (269,921.)

XIX.—Applications

Aische. Preparation of feeding-meals. 11,088. Apr. 26.

Bakes, Galloway, and Thaysen. Treatment of vegetable matter. 11,577. Apr. 30.

Tillisch. 11,114. See XII.

XIX.—Complete Specifications

29,686 (1925). Hunt. Making a self-preserving acid milk product. (269,610.)

2074 (1926). Munday. Sterilisation, pasteurisation, etc. of milk and other liquids. (269,678.)

*10,842 (1927). Avanzi. Preparation and preservation of fish and other products. (269,923.)

XX.—Applications

British Dyestuffs Corp., Ltd., Bunbury, and Shepherdson. 11,146. See IV.

Etabl. Poulenc Frères, and Fournau. Manufacture of ortho-chloro-para-aminoglycineamidephenylarsinic acid. 11,080. Apr. 25. (Fr., 21.10.26.)

L.-G. Farbenind. Making dihydroxyacetone. 11,186. Apr. 26. (Ger., 26.4.26.)

Inray (L.-G. Farbenind.). Manufacture of cyclic ketones of the aromatic series. 11,187. Apr. 26.

Soc. Chem. Ind. in Basle. Manufacture of derivatives of substituted quinoline carboxylic acids. 11,603. Apr. 30. (Switz., 30.4.26.)

XX.—Complete Specifications

235 (1926). Inray (Soc. Chem. Ind. in Basle). Manufacture of condensation products of urea, or a derivative thereof, and formaldehyde. (246,126.)

779 (1926). Hohn. Production of a chloride capable of reaction from pinene or purified turpentine oil. (269,624.)

1549 (1926). Newbery, and May & Baker, Ltd. Manufacture of unsymmetrically acylated amino derivatives of arylarseno compounds. (269,647.)

1930 (1926). Dicker (Deutsche Gold- und Silber-Scheideanstalt). Iodising pyridine derivatives. (246,501.)

2306 (1926). Râth. Production of 2-amino-5-iodopyridine. (246,842.)

2561 (1926). Putart. Synthesis of methyl alcohol and liquid hydrocarbons. (247,178.)

8672 (1926). I.-G. Farbenind. Manufacture of nucleal-alkylated or nucleal-cyclo-alkylated arylsulphonic acids. (250,241.)

*10,852 (1927). Chem. Fabr. vorm. Sandoz. Preparation of gall acids. (269,925.)

*11,186 (1927). I.-G. Farbenind. Making dihydroxyacetone. (269,950.)

XXI.—Complete Specifications

27,428 (1926). Wade (Wadsworth Watch Case Co.). Photographic processes. (269,806.)

*10,740 (1927). Klaver. Manufacture of photographic negatives and prints. (269,912.)

XXIII.—Application

Pennell. Purification of trade waste. 11,409. Apr. 29.

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number: *Austria*: Chemicals, printing machines (439). *British India*: Steel boiler tubes (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1.). *Canada*: Zinc sheets, glaziers' diamonds (432). *Germany*: Vegetable, mineral and animal oils and fats, oilseeds, oil-cakes, fish-meal, waxes (447). *Greece*: Metals, paper, printing inks, dyes, copper, tin, electric cable (450). *New Zealand*: Artificial silk (437). *Poland*: Leather, leather chemicals (452). *Spain*: Pharmaceutical chemicals, patent medicines

(456). *South Africa*: Wrought iron chain (A.X. 4626). *United States*: Creosote oils, coal tar, coal tar pitch, tar acid, cresylic acid, solvent naphtha and benzol (464); Glassware (465); Mining and engineering machinery (467).

News from Advertisements

A lecturer in chemistry is wanted by the University of Witwatersrand, Johannesburg, South Africa (p. viii).

A part-time research organiser is required by the Research Fund Committee of the Institute of Brewing (p. viii).

Two advertisers offer sets of the JOURNAL OF THE SOCIETY OF CHEMICAL INDUSTRY for disposal (p. viii).

Several patents are offered for negotiation (p. viii).

A mineral analyst, with foreign and colonial experience of buying ores, desires responsible appointment (p. viii).

A laboratory is required in London (p. viii).

No. 20

EDITORIAL

Empire Day

OFTEN in the past we have turned aside respectfully but determinedly from contributions which have related in verse how Carbazide when Iodide. With thoughts of Empire Day, of the Imperial Conference and the Colonial Governors' Conference, of the significance of the tour of the Duke and Duchess of York in Australasia in our mind, and with Anzac Day just past, we may be forgiven for longing for the soul of a Homer in order to write a worthy epic of Empire. The very materialism of much of a chemist's work compels him, happily enough, to consort with Art, Music and Poetry even though he may be merely a dilettante. Chemistry is not without its romance, its beauty—truth is beauty, beauty truth but its incidence upon humanity must be largely materialistic. So it is then that the function of the chemist in Empire development must be preponderatingly, but not by any means entirely, utilitarian. But it is no ignoble destiny, and provided we play our part well, we may be content to leave the song of Empire to be voiced by those more fitted to the task and put away vain regrets. Even in the comparatively early stages of the development of a new land, the products of the chemist, the metallurgist and the chemical engineer are of value to the pioneer for the construction of his railroads and bridges, his habitations and his townships, and for their maintenance. The development of mineral wealth and general natural resources, and the transformation and safe transit of natural products are matters in which the chemist and chemical engineer are vitally interested, whilst pastoral and agricultural occupations cannot long be carried on at full efficiency without insecticides and chemical manures even in virgin territory. The British chemical industries, through such agencies as Imperial Chemical Industries, Ltd., which reach to the uttermost corners of the Empire, are able to take their part in Empire development, but the time comes when internal chemical industries are created within the countries of the Great Commonwealth. Anyone who has glanced even casually through our recent Canadian number must realise the force and implication of this remark, and what has happened in Canada will be repeated in other Empire countries. Already in New Zealand, for instance, there is the seed of a second Shawinigan, for the New Zealand Nitrates Syndicate has been formed to

harness water power in the region around Dusky Sound and Deep Cove. With enormous amounts of cheap electrical power available it is inconceivable that development will cease at the production of nitrogenous fertilisers, and we may reasonably anticipate the growth of a large chemical industry making such products as demand electrical power in quantity at a cheap rate for their economical manufacture. We have but to remember the variety of chemicals made around Shawinigan Falls in Canada to realise the potential productivity of many of the Empire countries. For many years to come, however, the Mother Country may influence Empire chemical development in a very important manner, namely, by the "export" of research. The valuable work of the Department of Scientific and Industrial Research will bear fruit throughout the Empire, and this the more quickly and certainly if a workable scheme of co-operation between the home country and the countries of the Empire be put into operation. We have long advocated this in another place, and we note with satisfaction that it is to receive consideration at the Colonial Governors' Conference now in session. Many of the problems being studied under the control of the Department of Scientific and Industrial Research concern Empire life and industry as intimately as they do our own, and the results of research may be applied with equal profit. The savings possible in electric power transmission recently demonstrated by the Electrical Research Association, the work of the Stone Preservation Committee, the possibility of growing tung and perilla oil in the Empire, and the general improvement in the yield of palm products, the best means of shipping apples from Australia to this country, and the more general questions of food preservation by cold storage or canning, and indeed a score of examples which might be selected, indicate the value of research, carried out in this country, to the Empire at large. The results of such research would be useless, however, unless known far and wide to all likely to profit from their application, and it is to be hoped that it will not be long before an effective organisation for the dissemination of acquired knowledge throughout the countries of the Empire will be in operation. It will not be easy to create a detailed scheme, for even within the comparatively narrow limits of a single works' organisation we have

known the difficulties in applying to the full the definite results of a research department, but we are confident it can and will be done. The effective co-operation which has existed for some time between this country and the United States in fundamental coal research may provide a type of working base upon which we may shortly see erected an important and influential Empire Organisation for Scientific and Industrial Research.

Stone Preservation

It was our good fortune quite recently to visit several of our mid-county cathedrals and historic churches in the company of a rising young artist, who told us much of engaging interest about the art and craft of stained glass. It was gratifying to learn that both ancient and modern British stained glass productions—not to be thought of as mere pictures in glass—could claim the highest artistic merit. It was, therefore, with a certain sense of regret that we, as a humble member of a profession which justly claims to serve humanity in almost every phase of its complex civilisation, had to point out many instances of disintegrating stonework and decaying woodwork. Both plain majestic workmanship and beautiful or bizarre carvings of bygone artist craftsmen showed unmistakable signs of the action of time and circumstance, and we were not consoled until we read the recently issued Report of the Stone Preservation Committee which was appointed in 1922 "to report to the Building Research Board of the Department of Scientific and Industrial Research in regard to the best methods by which decay in building stones, especially in ancient structures, may be prevented or arrested, having regard to their function and to their original tooled surface." We recollect from articles which have appeared in our own columns that there are many recognised causes of stone decay, amongst which may be mentioned wind erosion, expansion and contraction with change of temperature, the freezing of water within the porous stone, the slow solution of calcium carbonate by water containing dissolved carbon dioxide, bacterial attack and, under modern conditions, the conversion of calcium carbonate in limestones and the like into sulphate through the agency of sulphur dioxide in the air and sulphuric acid, sulphurous acid and ammonium sulphate dissolved in rain water. Calcium sulphate formation is a two-headed giant of destruction, for not only can it be dissolved away so that in a sense rain water may actually be a solvent for stone, but also the production of sulphate crystals within the stone leads to powerful disintegrating forces being set up. How best can the ravages largely incident upon the presence of sulphur acids in present-day atmospheres be minimised? It would appear that the individual grains of porous stone must be coated with a protective layer so placed as not to diminish the porosity of the stone. Anything which tends to close the pores of the stone such as coatings of cement—not in any case aesthetically desirable—is dangerous. We may recall an interesting experiment of Professor Laurie's in which a piece of sandstone was coated with vaseline except on one upright face, so that the sample represented as far as possible the condition of stone in a wall. When this stone was played upon with a jet of water and allowed to dry, fresh crystals of salt, previously soaked into the

stone, were formed on the surface so that by repetition of the surface washing, the salt was entirely removed from the stone. On covering the free face with a layer of portland cement, however, crystallisation took place behind the cement, which was detached with simultaneous rotting of the stone. Many materials in solution may be deposited around the grains of stone without affecting materially its porosity, and the results of much careful experimentation are given in the report of the Stone Preservation Committee. Amongst these are paraffin wax of various melting points, silicate of soda, colloidal barium sulphate and synthetic resins of the phenol-formaldehyde class. The last-named appear to possess considerable interest, for although organic in nature, they are more resistant to acids and salts and to "organic" decay than ordinary natural rosin or colophony which, in solution in alcohol, has shown satisfactory results in the preservation of many stones. Professor Laurie reported in 1925 that experiments with rosin solutions upon sandstone had been in progress for some seven years, and that in no instance had scaling occurred, whilst in most cases rapid decay of the stone had not been observed. The synthetic resins seem to offer better coating means than rosin—which cannot, of course, be used upon limestone on account of the formation of lime soaps—but the deposition of a thin film of insoluble silica would appear to provide an almost ideal method of stone preservation. By the use of silicon ester, now a commercial product shown at recent exhibitions by Messrs. Albright & Wilson, of Birmingham, transparent layers of hydrated silica can be deposited upon the stone grains, rendering them almost immune from chemical or bacterial attack, and yet not affecting substantially the porosity of the stone as a whole. Silicon ester, made by the action of alcohol upon silicon tetrachloride, is a liquid which mixes readily with volatile solvents, and the solutions may be applied readily to stonework. The action of air and moisture brings about the necessary decomposition to hydrated silica. We have found no reference to extended experiments with silicon ester in the report of the Stone Preservation Committee, although on account of our real or fancied pressure of work, we have not been able to study the report exhaustively—and we wonder if the chemists of Messrs. Albright & Wilson, who have recently given us undeniable proof of their progressive outlook in other directions, could enlighten a large and interested public upon the value of silicon ester in stone-preservation. Finally, what has become of such materials as magnesium fluosilicate, which came so much into prominence a year or two ago, following glowing reports of their value upon the Continent? Was it Professor Desch who advocated its use in this country upon the basis of its reaction to form magnesium and calcium fluorides and silica within the stone treated? The preservation of the stonework of our beautiful and historic buildings is a matter which commands the attention of all. Spread throughout the Empire there are stately buildings which merely need that stitch in time in place of the nine which we in this country must make—and in the end it is the chemist's responsibility. The Building Research Board has instituted and reported the results of much valuable work, but in the matter of stonework preservation and renovation much still remains to be done.

DRIERS AS APPLIED TO PAINT AND VARNISH

By CLAUDE E. WATSON

(Concluded)

With the lead compounds, it is found that litharge is soluble at a lower temperature than red lead and gives a much paler solution, but when the oil with litharge is carried to the same heat as the red lead oil, the colour is practically the same. However, in a drying test, the litharge oil carried to 450° F. for 30 mins. dried fastest, the litharge oil carried to 400° F. for 30 mins. came next, while the red lead oil was the slowest. All three samples showed a sediment in the bottom. This is due to the lead compounds separating out of solution, a peculiarity of lead driers, which can be lessened to a great extent by high temperature or long heating, preferably the latter, because, as demonstrated with litharge, the solution becomes more stable. For this reason many prefer to use red lead, claiming that, because it requires more heating to get it into solution, therefore the solution will be more stable, but from the above experiment this does not seem to be the case. In our practice, we used litharge because we found that by regulating our heat we could get paler solutions than when using red lead. However, in two other samples the resinate and linoleate of lead were used, and it was found that they go into solution on heating at 350° F. for 30 mins., the resulting oil containing less sediment and drying faster than either the litharge or red lead oil.

We will now examine the manganese driers. Eleven different samples were prepared with the different manganese compounds so that each sample contained the same percentage of the element calculated as metal. When manganese dioxide was heated to 475° F. for 30 mins. there was practically no solution, but when heated to 500° F. for 30 mins. some of the metal had gone into solution. When these samples were poured on glass it required 36 hrs. for the former to dry, and 16 hrs. for the latter. Using manganese carbonate, we get very interesting results. It is claimed that using this material as a drier will give pale oils. Tests showed that when heated to 475° F. for 30 mins. the oil is pale, but there is sediment, i.e., drier that did not go into solution; when carried to 500° F. for another 30 mins. the oil is darker and there is still some of the drier not in solution; heating to 600° F. for an additional 15 mins. causes the drier to go into solution, but the resulting oil is very dark. Instead of carrying to the higher temperatures a sample was held at 475° F. for 8 hrs. with continual stirring; there was still a slight sediment, and the oil was very dark. When these samples were poured on glass it required 17 hrs. to dry the first two; 19 hrs. to dry the third, and 16 hrs. to dry the fourth. The third was slower drying because the film was very heavy, due to polymerisation at the high temperatures used. The fourth sample was polymerised to a certain extent, and gave a heavier film than the first two, but, because there was more drier in solution, it dried faster. It is quite apparent from this that manganese carbonate, if taken into proper solution, will not give pale oil. The same applies to some samples of manganese hydrate. With the acetate, it requires 30 mins. at 380° F. to give an oil which dries in 15 hrs.

With the resinate and linoleate, we find entirely different results; they go into solution on heating at 350° F. for 30 mins., and the linoleate gives the palest solution; when poured on glass they were both dry in 13 hrs. Here again the linoleate and resinate give better results than the other manganese compounds.

Upon testing the cobalt compounds it was found that the oxide is practically insoluble even at 600° F. There was very little change in colour of the oil, while the unaffected oxide had settled to the bottom. When poured on glass this oil was a little faster in drying than the original oil without drier. The acetate goes into solution on heating at 380° for 30 mins., but leaves some sediment, and when poured on glass required 13 hrs. to dry. The linoleate and resinate go into solution on heating at 350° F. for 30 mins., and dry in 12 hrs. There is no difference in colour with the last three, but it is still shown that the linoleate and resinate are the best driers.

From the foregoing tests, I believe that I am justified in saying that while there are still a few places, especially in varnish making, where some of the raw materials are essential, the use of the linoleates and resinates in the majority of paint and varnish work is the best practice where quality and uniformity are required.

Since the lead driers are too slow by themselves, and yield tacky films, whilst the manganese and cobalt driers by themselves yield films which have surface-dried, they are very rarely used alone. To get efficient driers it is essential to use combinations either of lead and manganese, lead and cobalt, or lead, manganese and cobalt. It is very rare that manganese and cobalt are used in combination, because for most work it is very unsatisfactory. We find that best results are obtained with combinations which contain lead in the highest percentage. We make different kinds of driers, but our main driers are a concentrated lead drier, using lead resinate, a combination drier using lead resinate and manganese linoleate, and a concentrated cobalt drier using cobalt linoleate. We know the proportion of metal present, and therefore can make any combinations necessary to give proper drying results. You will no doubt wonder why I say that lead should be present in the highest percentage. We proved this in both our paint and varnish.

For some years we had trouble through a certain exterior paint losing its gloss after a few months of weathering, while a certain exterior varnish would persist in checking and cracking after comparatively short periods of exposure. We were using the best of materials in both of these products, and could not understand why they should not stand up better than they did. We checked over everything, testing it very carefully, until we eventually came to the drier.

The drier used in the paint was made by dissolving manganese dioxide and litharge in oil, and then thinning this with turpentine. The drier contained lead in the highest proportion, but we found that, when added to linseed oil and then allowed to stand for a long period, there was considerable light-coloured precipitate on the bottom of the container. Upon examining this, it was found to consist of lead compounds which had separated from the oil. This left the oil with a drier that contained

a greater proportion of manganese than should be present with the lead that was left. When the oil was tried for drying time, it was found to be somewhat slower drying than when first made, and when it did dry the effect of the manganese present was apparent because it was surface dry. We, therefore, rightly concluded that the same process was taking place in the paint; because it dried mostly on the surface this part of the film would break down much more rapidly, and, therefore, cause the paint to become dull. After several tests on driers we made one from lead resinate and manganese linoleate in the proportion of ten to one, calculated as metal, because we found this to give a film which dried throughout, and therefore held its gloss for much longer periods.

The drier used in our varnish was a different proposition; here lead was incorporated by using litharge on the down heat, and instead of manganese we used cobalt, which was employed as a liquid cobalt linoleate solution put into the varnish after it was thinned. The two elements were present in about equal proportions. We had no trouble with precipitation of lead in this case; the trouble was due to an excess of cobalt, which caused the film to surface dry, leaving the lower portions more or less unoxidised, with the consequence that as the surface became harder and harder, it eventually contracted so much that the under layer, being softer, was unable to hold it in place, and it cracked.

I have already mentioned that the lead driers have a tendency to separate upon standing. This is a peculiarity which it is almost impossible altogether to overcome. However, with great care it can be held to a minimum. Manganese or cobalt give very little trouble in this respect. The reason for this is that when the lead drier is added to oil the lead will combine with the stearates and other saturated acids present in the oil, and these compounds being insoluble will gradually appear as a cloud in the oil, and upon standing will eventually precipitate. This fault is more apparent when the drier has been made from litharge, red lead, or lead linoleate and oil. When resin or resins are present, the precipitate is greatly reduced because the lead compounds of the saturated fatty acids are more soluble in the rosin acids. For this reason lead resinate finds an extended use, but here care must be exercised to obtain normal lead resinate and not basic lead resinate, because the latter, while soluble in hot resin or resins, is not soluble in oils or volatile thinners.

At the beginning I made reference to the care which should be exercised in the use of driers. It has been proven that 0.04% of cobalt, 0.1% of manganese or 0.67% of lead calculated as metal when used alone and in proper solution is enough to dry linseed oil in from 12 to 16 hrs. These are practically the optimum amounts of the metals which should be used. To use more than these amounts, except in the case of lead, will not give faster drying. Lead up to 1% shows faster drying, but leaves a very tacky film, whilst manganese, if used much over the optimum amount, will retard drying.

In making paint and varnish we endeavour to avoid excess driers and, since we always use combination driers in our products, do not experience any difficulty in keeping any one metal below its optimum percentage,

but there are times when we do experience trouble in keeping the metals properly balanced owing to the many variables which enter both in the making and using of these materials.

It was found that raw linseed oil with 0.38% lead and 0.038% manganese, or 0.38% lead and 0.034% cobalt, or 0.38% lead, 0.019% manganese and 0.017% cobalt calculated as metal, would dry in 5 hrs. at 70° F. It did not make any difference whether these materials were used as resinates or linoleates, only it was noted that it required longer heating to get the linoleates into proper solution. When the above percentages are reduced by $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$ and $\frac{1}{4}$, respectively, the drying times were 5½ hrs., 7 hrs., 10 hrs., and 16 hrs. at 70° F. It will no doubt seem that 5 hrs. is quite rapid drying; however, when the same oil is tested at 60° F. it requires 10 hrs. before it is dry. You may imagine, then, how slow-drying the oil with the reduced drier would be. This brings me to one of the most uncertain variables we have to deal with, namely, temperature. It is from this source that most complaints come regarding slow-drying paint or varnish. It is impossible to make paint or varnish products which will work satisfactorily at all temperatures. If made to dry in from 8 to 10 hrs. at 60° F., it is too fast-drying at 70° F., while if made to dry in 8 to 10 hrs. at 70° F., it is far too slow-drying at a temperature of 55° to 60° F. This trouble is much more apparent on interior painting than on exterior work because of two more variables which enter, namely, ventilation and sunlight. Poor ventilation means poor drying. To prove this statement a board was painted on both sides with the same paint. This board was hung up inside, so that one side was within an inch of the wall while the other side was exposed to the room. It was found that the side next to the wall required 4 hrs. longer to dry than the other side. The reason is simple enough. The air over one side was changed rapidly while the air over the other side was not. It is partly through this that a paint will dry faster outside than inside with the same temperature.

The greatest reason for the paint drying faster outside, as a rule, is sunlight. On a bright sunny day, paint will dry much more rapidly than on a dull, humid day, even though the temperature is the same. This is owing to the accelerating effect which the ultra-violet rays of sunlight have on the drying of paint and varnish.

There are two other variables which affect the use of our product, thickness of film, and the surface over which it is applied. The former depends entirely upon the individual applying the material, but a thick film will require much longer to dry than a thin film, and when the film is dry it will break down much more rapidly owing to surface drying. Therefore, the best practice is to apply thin films.

The surface is a very important source of complaint at times. Traces of any grease, wax, paraffin oil, etc., will in varying degrees slow up the drying of paint or varnish films. For this reason, washing soda and not soap should be used to clean off grease spots, while benzine will remove wax and oil from painted or varnished surfaces. Different surfaces will influence the drying of the same material, that is, wood, metal, canvas, etc.

practically all require paints made specifically for the purpose.

The following three variables also enter into the making of the product: the kind and quality of oil, the pigments used, and the length of time that the drier has been mixed with the oil.

The kind and quality of the oil refers to whether it is linseed, china wood, perilla, fish, or soya bean, and whether it is an old oxidised oil, a blown oil, a polymerised oil, a fresh raw oil, or a boiled oil. Many combinations of the above oils are used. Wood oil and perilla are generally used as polymerised oils; linseed, fish, and soya bean oils are used in all forms. The last two are very slow-drying and require special combination of the driers, which generally contain higher percentages of cobalt than is necessary for the other oils.

The pigments used have a considerable bearing upon the drying of paint. To test this, paints were made up using the same oil throughout and the following pigments: para-nitroaniline red, silica, asbestine, barytes, white lead, lithopone, zinc oxide, ochre, chrome green, ultramarine blue, antimony oxide, carbon black, iron oxide, umber, lead chromate (yellow), and Chinese blue. These paints were made of the same consistency, so that when applied we would get the same thickness of film. The drying times ranged from 6 hrs. for lead, zinc, and lithopone, to 26 hrs. for Chinese blue at 70° F. Para red, silica, asbestine, and lead chromate do not affect drying. Ochre, chrome green, ultramarine blue, antimony oxide, and carbon black slow up drying somewhat because they required practically 9 hrs. to dry. Iron oxide, umber, barytes, and Chinese blue slow up drying considerably, the first requiring 13 hrs. to dry, the next two 17 hrs., and the last 26 hrs. It is quite apparent that some pigments inhibit the drying reaction. This may be due to preferential adsorption of oxygen by the pigment, or it may be due to some impurities in the pigment which poison the catalysts.

A last factor which has a bearing on drying time is the length of time that the drier has been mixed with the paint or varnish. To add drier and then use the material immediately is poor practice, because it requires time for the drier to combine with the oil to cause efficient drying. We usually allow at least 12 hrs. when the drier is added cold. But, wherever possible, we prefer to combine the oil and drier with heat, and then store in tanks ready for use. Manganese and cobalt combine quite rapidly, whereas lead combines quite slowly in the cold. Therefore, when the material is used shortly after adding dryer the result will be slow drying, and the drying that does take place will be surface drying.

Keeping the variables in mind, it is not hard to understand why we are tempted at times to use excess driers or combinations of driers which we know will not give best results, in order to make our products dry under diverse conditions to suit many people who do not, and will not, take these factors into consideration when using paint or varnish. If your product is slow-drying, no matter what other qualities it has, you are immediately condemned.

The choice of driers is a matter which has to be carefully considered, especially in products for interior

use. In white paints, very light colours, or white enamels, it is best to avoid manganese drier and use a combination of lead and cobalt, because manganese causes much more rapid yellowing, owing to the fact that it causes the ultimate oxidation product to form much more rapidly than do the other driers. It also gives a pink cast to the whites when first applied.

In closing, I wish to thank the Harshaw, Fuller & Godwin Company, of Cleveland, and the Dominion Linseed Oil Company, of Montreal, for their co-operation, which has assisted materially in developing the experimental work of this paper.

THE INTERNATIONAL CONFERENCE ON BITUMINOUS COAL AT PITTSBURGH*

By DR. R. LESSING

In the summer of 1926, when the social and industrial life of this country was threatened by the most gigantic struggle in its economic history, and the contending parties were waging the fierce fight for hours and wages, with little regard for the fundamentals of the industry, the high-minded President of the Carnegie Institute of Technology, at Pittsburgh, Pa., Dr. Thomas Stockham Baker, undertook the organisation of an International Conference for the consideration of the scientific and technical aspects of coal and its utilisation. In doing so he was mindful of the principle laid down by our own Royal Commission on the Coal Industry (1925) in the final conclusion of their monumental Report, according to which they gave pride of place amongst the three chief lines of advance towards prosperity in the industry, to the greater application of science to the winning and using of coal.

The coal problem is essentially a world problem, and no phase of it can be duly considered without regard to its international aspect. The United States of America, in spite of its vast natural resources, its geographical advantages, its financial independence and its present unprecedented prosperity, is by no means free from anxiety in the development of its own coal industry, and in its turn has been faced for the past four months with the possibility of a coal stoppage arising out of the termination, on March 31 last, of the existing mine wages agreement, known as the Jacksonville agreement. In America, as in this country and on the Continent of Europe, the expansion of industrial activity hardly keeps step with the advances made in the more efficient and more economical utilisation of coal; this factor, coupled with the competition of other sources of energy, calls a temporary halt to the increase in the output of coal from the world's mines, which are continually threatened with the possibility of over-production. Thus, a double incentive is given to the intensified study of the coal problem, on the one hand by the consumer, who is forced by progressively keener competition to more and more stringent economies in his coal requirements for the supply of energy or raw materials, and on the other, by the producer, who is compelled to compensate a shrinking or non-expanding volume of output by the

* Read at a joint meeting of the London Section and the Fuel Section on April 4.

cheapening of production, and the enhancement in value of his product.

The conference was organised to take stock of the existing knowledge of practical fuel technology, to acquaint workers on the other side of the Atlantic with the work done in Europe in this branch, and to stimulate research on the coal problem in America. It must be recognised that in America industrial research has reached a high order, both quantitatively and qualitatively, and that it is contributing in no small degree to the phenomenal prosperity which that country enjoys at the present time. The proposal to hold a conference on coal fell, therefore, on fertile soil, and as a proof of the enthusiasm with which the idea was received, it may be mentioned that the conference was attended by over 1700 persons, among whom were official delegates from 162 colleges, learned societies and governmental bodies in the United States and ten foreign countries, quite a number of "captains of industry," and most of the leading fuel technologists and research workers of America.

The conference constituted a fine tribute to the organising ability and power of President Baker, who had the loyal support of the staff of the Carnegie Institute of Technology. Enthusiasm was the keynote of the meetings occupying morning, afternoon and evening sessions during the four days from November 15 to 18, 1926, in which an almost overwhelming mass of useful scientific and technical information came forth.

It is hardly possible to give within the time available even a brief résumé of the 43 papers submitted—or of the discussions, opened in every case by a specialist of the subject; their contents are about to be published in full,[†] and it will therefore suffice to sketch the outstanding features and to follow the general trend of thought given to the various groups of subjects.

The conference was opened by an address by Dr. Baker, who dwelt on the need for the scientific treatment of coal utilisation. He foresees that in less than a generation the present methods of shipping coal to be burned in its raw state under boilers hundreds of miles from the mines will appear to have been primitive and rudely unscientific. To this end research must be encouraged as a national duty, and far-sighted men of affairs must perceive that something more than financial resources is necessary for commercial progress. Modern business demands two kinds of capital, money, and technical and scientific knowledge. A well-organised and well-directed staff of research men can achieve results in a business way which cannot merely be secured by great credits.

Dr. Baker's statesmanlike pronouncement emphasised what must impress any unbiassed student and observer of American industrial life, that, contrary to the current European belief, its rapid development is not entirely or exclusively due to unrestricted financial liquidity, helpful and comforting though this factor may be, but largely to hard and unremitting work and the steadily increasing adoption of scientific methods.

COAL SUPPLIES

The list of papers presented was appropriately headed by a comprehensive statement on the quantity, quality, and distribution of American coals by Dr. M. C. Campbell, of the U.S. Geological Survey. Although about 50% of the visible coal supplies of the world is located in the United States, Dr. Campbell recognises the need of conserving these resources, and particularly of utilising coals of low "rank" available in many regions where high freight rates prohibit the shipment of better coals. The coal classification adopted was illustrated by representative analyses of the coals of various ranks occurring in the numerous fields. To realise the variety of coals available in America, it must be remembered that, on the basis of an assumed ash content of 8%, their fixed carbon varies from 25% to 90%, the moisture from 45% to 1%, and the calorific value from 6000 to 14,500 B.Th.U. Dr. Campbell's detailed discussion of the different varieties occurring in practically all fields will be found useful as a permanent record for future reference.

COAL RESEARCH

Though it may be taken for granted that all the material submitted to the Conference was the outcome of an immense amount of research, two papers dealt specifically with the aspects of coal research itself on national lines. Dr. C. H. Lander gave an account of British research on fuel utilisation. He described the organisation of the Department of Scientific and Industrial Research in general, and of its Fuel Division in particular, and the work done at the Fuel Research Station at Greenwich. This work is too well known to require more than casual mention here, but it should be stated that the results of this work, which, after the early years of organisation and preparation, is only now beginning to make itself felt, are greatly appreciated, beyond the confines of the Empire, by those interested in fuel matters. Dr. Lander gave a detailed account of the physical and chemical survey of British coals, of work on the problems of carbonisation at high and low temperature, steaming in vertical gas retorts and carbonising tests in horizontal retorts. An historical account was given of the work on low-temperature carbonisation done at Greenwich, and the tests carried out on commercial plants were detailed. The new Bergius plant and researches carried out in co-operation with other bodies and individuals were mentioned.

Mr. A. C. Fieldner, the Superintendent of the Pittsburgh Experiment Station, U.S. Bureau of Mines, in a suggestive paper on the practical value of fundamental coal research dwelt on the meagre support given to it until recent years. He cited British coal research as a concrete example of the fundamental work he had in mind, a compliment which we in this country must appreciate all the more as coming from the chief of an institution which in its twenty odd years of existence has led other countries in producing an immense amount of valuable data, standard methods of testing, and practical suggestions in mine-safety work and in all branches of fuel utilisation. Mr. Fieldner proposed a programme of coal research, taking as his model the extensive programme of research on petroleum which the American Petroleum

[†] "Proceedings of the International Conference on Bituminous Coal. New Developments in Utilisation." Published by the Carnegie Institute of Technology since the paper was read.

Institute was enabled to undertake by two grants of \$250,000 each from John D. Rockefeller and the Universal Oil Products Company. Fieldner finds that 22 out of the 31 projects for research on petroleum are applicable to coal and its products. While much of this work has already been done by individual investigators, and in recent years by organised groups in America, England, France and Germany, these research institutions in the aggregate represent but a modest beginning, and their total annual expenditure is small compared with the money lost each year on futile commercial experimentation.

OTHER PAPERS

The papers incorporating practical proposals or reporting actual achievements dealt with the following phases of the fuel problem: Liquefaction of coal; powdered coal; low-temperature carbonisation; gas manufacture; smokeless fuel; coal tar; fertilisers; power production; and mineral constituents of coal.

The trend of present-day thought in fuel matters, as exemplified by these contributions, showed a distinct bias towards the conversion of coal into oil and the application of solid fuel in powder form. At first sight it might seem surprising that America, the land of prolific petroleum production, should show such vivid interest in the problem of producing oil from coal.

The reason must be sought in the astounding growth of mechanical road transport. Rating the 20,000,000 automobile engines in the United States at the conservative average of 20 h.p. each, a combined capacity of 400,000,000 h.p. is obtained, which, according to reliable statistics, is about one-half of the capacity of all the power-developing equipment in the country, and three times that installed on the railways. Fortunately, motor-car engines are run under full or even partial load for a very small average period out of the 24 hrs., say, about 3% of their capacity. Even so, the consumption of motor fuel is so large and so rapidly increasing that the problem of procuring future supplies is a very serious one, even if allowance for a large addition by cracking of heavy oils is made. Hence the intense interest taken at the Conference in the liquefaction of coal, the synthesis of hydrocarbons, and the recovery of liquid fuels by carbonisation.

LIQUEFACTION OF COAL

Dr. F. Bergius gave an account of the conception, elaboration and translation into a practical process of his method of direct liquefaction of coal by means of hydrogenation. He restated the considerations which guided him in his early work, viz., that it was necessary to strike a balance between the addition of hydrogen to the coal substance and its destructive distillation. Within a certain range of temperature the velocity of hydrogenation is greater than that of the carbonising reaction, but at higher temperatures the latter is faster and, finally, yields coke instead of oil, even at pressures under which the hydrogen is brought into the closest contact with the coal. When treated at 300–350°, a kind of high melting pitch is produced, which by continued treatment at 420° and under 200 atm. pressure is liquefied, giving a yield of from 40% to 70% of oil, according to the kind of coal used. From an average

bituminous coal, 15% of motor spirit, 20% of middle oil, 6% of lubricating oil, and 8% of fuel oil can be obtained. Dr. Bergius recounted the engineering difficulties which had to be overcome, involving years of research and large financial risks. He also showed that economically "Berginisation" may be considered in combination with other processes. By using coal tar or primary tar as the oily medium for preparing the coal paste fed into the autoclave instead of the oil or tar made in the process, it may be hydrogenated to form Bergin products. Again, the gas liberated in the process may be used as town's gas and a Bergius plant may be combined with an ordinary gas works or coke ovens. The coke produced would be converted into water-gas and hydrogen, and the final products of the combination would be oil and a gas of high calorific value.

Prof. Franz Fischer attacks the problem of liquid fuel supply from a different angle. In his paper he gave an excellent, concise summary of the previous work on catalytic reactions of carbon monoxide under high pressure, referring to the manufacture by the Badische Company of methanol and to his own method to produce synthol and synthin. Considerable interest was shown in Fischer's account of his and Tropsch's work on the synthesis of petroleum products from water-gas at atmospheric pressure. The simplicity of the method by which, according to the selection and preparation of the catalyst, and the control of temperature, the production of methane may be suppressed in favour of liquid hydrocarbons of varying boiling range, is very considerable, and outweighs, according to Fischer, the greater bulkiness of catalyst chambers required. Any gases containing carbon monoxide and hydrogen, e.g., water-gas, producer gas or blast furnace gas may be used as raw material. Fischer proposes, in the first instance, a single passage of water-gas over the catalyst, when 100 g. per cb. m. of solid, liquid and readily-liquefiable hydrocarbons is obtained and the use of the permanent gas, which has a high calorific value, for the ordinary town supply, alone or in admixture with coal gas or water-gas.

General G. Patart, the French Inspector-General of Explosives, presented a carefully-prepared survey of the work on the production of liquid fuels from coal, and particularly of his own process for the catalytic synthesis under pressure of alcohols from water-gas. Photographs of the semi-commercial plant at Vitry-sur-Seine were shown, which is the model of larger installations to be erected in France and America. Patart's proposals also embrace, as do those of Fischer and Bergius, the suggestion that these processes should be grafted on the ordinary gas works routine. The water-gas of special composition required for alcohol synthesis is to be taken from the ordinary water-gas generator, whilst the residual gases after removal of the alcohol are returned into the ordinary gas mains.

The dictum of the late Sir George Beilby that "the existing gas works certainly ought to be the natural nursery for the development of low-temperature carbonisation" applies, therefore, in the view of such pioneers as Bergius, Fischer and Patart to their respective methods of liquefaction or synthesis.

POWDERED COAL

The high heating efficiencies obtainable by the combustion of gaseous and liquid fuels have stimulated the desire to confer similar advantages on solid fuels by burning them in finely subdivided form, so as to present to the oxygen a surface many times that of an equal volume of lump coal, and thus induce rapid combustion. H. Kreisinger dealt with the latest achievements of powdered coal firing practice. Refractory furnace walls subject to slagging by coal ash had to give way to water or steam-cooled walls, which permit much greater turbulence and hence more intensive combustion and higher temperatures. A favourite form of water-cooled wall is constructed of fin tubes which form, for instance, the front wall of the high-pressure boiler at Lakeside, Milwaukee. The details of this giant boiler, designed to generate steam at a pressure of 1200 lb. per sq. in., and developing in actual work 1340 lb. pressure, are as follows:—

Hourly evaporation ..	240,000 lb.
Total water heating surface ..	30,070 sq. ft.
Superheating surface ..	930 "
Reheating surface ..	933 "
Air heating surface ..	40,320 "

The steam generated is superheated to a temperature of 720° F. It is then expanded in a high-pressure turbine to 300 lb. pressure and 420° F., and passed through the reheater, where it is heated to 720° F. and discharged into the main steam line of the plant to be used in the other large turbines.

In Wood's steam generator, erected at the works of Taylor Bros., Ltd., at Manchester, a large part of the boiler forms four high metal tube walls built round the furnace, in which the tangential arrangement of the eight burners produces turbulence of such intensity that 40,000 B.Th.U. can be liberated per cu. ft. of combustion space per hour.

The contribution by W. E. Trent, though not recording commercial achievements, was highly suggestive. According to him, coal may be readily disintegrated in a pulveriser, in which small steel balls are electrically vibrated 60 times per second through an amplitude of $\frac{1}{8}$ in., to pass a 300-mesh screen and even to smaller sizes. Thus finely-divided coal may be pumped through pipes without air as a carrying medium, by heating it so as to liberate water vapour or primary products of decomposition. It is then said to be in a state of great mobility, somewhat on the lines of Leidenfrost's phenomenon. Trent suggests carbonising ultra-fine coal powder flowing through retorts, as it were, in liquid form.

Prof. A. H. White recorded a laboratory investigation on the instantaneous carbonisation of powdered coals on the lines of the work on "cenospheres" of Newall and Sinnatt in this country.

The commercial elaboration of this problem in the McEwan Runge plant was described in an interesting paper by Dr. W. Runge. The plant, which is the third in order of progressive development, is erected at Lakeside on the premises of the Milwaukee power station. It consists of two retorts superimposed one on the other, each about 6 ft. 9 in. in diameter and 40 ft. high, with a funnel-shaped top. They are heated internally by burning coal gas in auxiliary combustion chambers connected tangentially with the bottom of the retorts, coal being dried and preheated in the upper

retort and carbonised in the lower. The coke is only partially cooled and pumped still warm to the boiler house. The plant, which is designed for a throughput of 8 tons per hour, is an extremely interesting one, and, provided removal of dust by the gases and caking of the coke powder can be avoided, the process should be a promising preliminary to the direct burning of the uncarbonised coal powder.

LOW-TEMPERATURE CARBONISATION

The problem of low-temperature carbonisation of compact coal as distinct from powder agitates the mind of American fuel technologists no less than that of their European confrères, as was manifested by the dozen papers presented to the conference on the subject. Contrary to the opinion held in some quarters that the provision of a smokeless fuel is of particular interest only to this country on account of the open domestic fire peculiar to the British home, it is found that this desideratum applies to America with equal force. True, domestic heating appliances there are of a kind producing less smoke, but the happy circumstance that anthracite or "hard coal" is available in enormous quantities—the annual output is about 60,000,000 tons as against 5,000,000 tons in England—has brought about the preferential use of smokeless fuel, at any rate in the Eastern States. The high market value which this commodity commands has created a desire among the producers of bituminous coals, and particularly those of the Middle-West, to enhance the value of their product by converting it into a robust smokeless fuel, and incidentally recovering by-products. As a large section of the American public has been educated to appreciate the advantages of smokeless fuels, the problem is perhaps an easier one there than in this country.

The economic aspect of low-temperature carbonisation was ably discussed by Dr. Horace C. Porter, whose conclusions tally closely with those submitted to the Samuel Commission by the Director of the Fuel Research Board and given in evidence by the writer.

The paper by Prof. S. W. Parr, the doyen of American coal investigators, was of particular interest, partly on account of its attractive historical preamble, and partly because the practical process he outlined is based on the thermal pre-treatment of coal (in a rotary drum), a feature which is the keynote of a number of the proposed methods.

Time does not permit more than a casual mention of the various types of plant or process. T. V. McIntire described his process, based on Smith's Carbocoal plant, which is in active and fairly successful operation at Fairmont, West Virginia. Coal is carbonised while agitated in a primary retort, and the semi-coke is briquetted and reheated to 1000°—1200° F. in a secondary retort.

Harald Nielsen gave a full account of the English L. and N. process and its internally heated rotary retort, and emphasised its capacity of yielding a true primary tar containing good lubricants in its higher fractions, together with a semi-coke which has been successfully burned in powder form.

Other forms of rotary plants described were C. B. Wisner's Carbocite retort, in which the coal is rolled into coke balls. W. A. Darrah's externally heated drum,

based on the German Thyssen process, and the K.-S. double drum type, described in a paper by Dr. F. Mueller (not read).

R. B. Parker dealt with the Bussey plant of the internally heated shaft type, similar to Maclaurin's retort and fitted with a reciprocating water-cooled cutter-bar discharge mechanism, interlocked with the coal-feeding device at the top of the shaft.

E. H. Piron's description of the Piron-Caracristi process of carbonising a thin layer of coal on a conveyor heated by a lead bath is valuable as a faithful account of failure. The difficulty of avoiding leakage of molten lead and mechanical troubles led to the shutting down of the two plants at the Ford Motor Works at River Rouge and Walkerville, but it is intended to have an improved smaller plant erected in Italy. The semi-coke obtained in a thin crust does not meet the requirements for a robust smokeless fuel, but could, after pulverisation, be used for boiler firing.

F. C. Greene described the Greene Laucks retort, in which the coal is propelled upwards by means of an ingeniously designed worm screw. One of these plants has been in operation on Illinois coal, and an improved pattern is to be erected, which incorporates some interesting engineering problems.

GAS MANUFACTURE

Mr. G. M. Gill gave a comprehensive survey of the present methods of British gas-making practice and the economies of the gas industry.

W. H. Fulweiler addressed himself to the subject of water-gas manufacture, dealing particularly with the pier process for gasifying coal, in which the fuel bed throughout its cross-section is kept active by a refractory pier in the centre of the generator, thus avoiding an uncarbonised core.

C. J. Ramsburg showed the construction and method of working of an entirely automatically operated water-gas producer with mechanical charging and clinkering mechanism.

SMOKELESS FUEL

The general proposition of "smokeless fuel" was developed by Mr. O. P. Hood, of the Bureau of Mines, whilst Mr. Osborn Monnett showed that the smoke problem in towns is in a large measure due to the low-temperature domestic fire. The city of St. Louis provides a school for instructing householders and their staff in the proper management of heating appliances.

COAL TAR

The papers on coal tar form a useful complement to those presented at the same time to this Society at the Manchester Tar Conference. The majority of authors treated the problem more from the economic than the technical side. M. Jean Bing gave a picture of the French tar industry in relation to that of other countries. S. R. Church, J. M. Weiss and R. M. Crawford described various phases of American tar disposal. They unanimously condemn the inadequate utilisation of coal tar in America. A large portion of coke-oven tar is burned in steel works, although, according to Crawford, a preliminary extraction of tar acids would be remunerative, whilst large quantities of tar are converted into tar coke in discarded beehive ovens.

Dr. Y. Oshima read a paper on the origin of coal-tar naphthalene, and gave experimental support to his theory for its formation from phenols.

G. Egloff called attention to the cracking of primary tar from low-temperature carbonisation of coal by the Dubbs process, which promises considerable supply of motor fuel of high anti-knock properties.

FERTILISERS

One section of the Conference was entirely devoted to the consideration of the production of fertilisers from coal, and the aspect of coal as a source of ammonia and its relation to the world's agricultural requirements was discussed in a series of papers by F. G. Cottrell, H. A. Curtis, L. C. Jones and C. J. Brand as representing the governmental, academic and industrial points of view.

POWER PRODUCTION

A subject of intense interest to us in view of the establishment of the Electricity Board and the coming reorganisation of the coal mining industry is Mr. G. A. Orrok's communication on "Mouth of mine power stations." On the basis of concrete examples, he discusses the advantages of proximity of power stations to the fuel supply and to the point of consumption of current, but considers that an adequate water supply is the deciding factor.

MINERAL MATTER IN COAL

I had the privilege of submitting to the Conference a paper on "Coal and its mineral matter," the only contribution dealing with this problem. Coal ash forms one of the most serious obstacles to high efficiency in fuel utilisation, and is the fundamental factor of distinction between solid and liquid or gaseous fuel. I endeavoured to show the differences in composition and distribution of the ash-forming components of coal, and to trace the part they play in its formation, winning, preparation, cleaning and utilisation. The economic significance of coal ash is beginning to be realised, and the catalytic influence which inorganic compounds exert on all processes of combustion, carbonisation and hydrogenation is slowly but surely finding recognition.

The Conference proved an unqualified success, and the general tenor of the contributions it called forth gave weight to the opinion that we are on the threshold of a new era in the utilisation of coal, and that the possibility foreshadowed of refining the natural product, of concentrating its intrinsic values, and of applying it in novel ways, is rapidly changing our conception of its potentialities, and makes one realise that we are witnessing the beginning of a revolution in the application of our principal source of energy.

CANADIAN PULP AND PAPER INDUSTRY

The Kipawa mill of the Canadian International Pulp and Paper Co., which supplies the greater part of the pulp for rayon manufacture in America, and also exports it to many other countries, is situated on the Ottawa river, at Temiskaming, Quebec, 230 miles above the city of Ottawa. This mill has a daily capacity of 250 tons highest grade sulphite pulp. The company has 4000 sq. miles of Crown-leased lands tributary to the Kipawa mill, the wood being almost exclusively spruce.

SOCIETY OF CHEMICAL INDUSTRY

President : FRANCIS H. CARR, Esq., C.B.E.

FORTY-SIXTH ANNUAL MEETING

to be held in

Edinburgh, 4th to 9th July, 1927

PROGRAMME OF ARRANGEMENTS

Monday, July 4

8 to 10 p.m. The North British Station Hotel. Informal Reception by the Chairman, W. A. Williams, Esq., and Committee of the Edinburgh and East of Scotland Section, followed by *Conversazione*. (Light refreshments will be served.)

Tuesday, July 5

9.30 a.m. Committee Room, University Union Council Meeting.

10 a.m. - Debating Hall, University Union. Welcome by the Lord Provost of the City of Edinburgh. Welcome on behalf of Edinburgh University by the Vice-Chancellor, Sir J. Alfred Ewing, K.C.B., F.R.S. Annual General Meeting of The Society of Chemical Industry (for Members only). Presentation of the Society's Medal to Lieut.-Colonel G. P. Pollitt, D.S.O.

11 a.m. - Debating Hall, University Union. Address by the President, Francis H. Carr, Esq., C.B.E., on "Industrial Chemistry and Progress in Medicine." A panoramic photograph will be taken in the quadrangle of the Medical Buildings, The University, immediately after the President's Address.

1.15 p.m. - The North British Station Hotel. Luncheon by invitation of The Edinburgh and East of Scotland Section. Representatives of the Edinburgh Town Council and of the Universities of Edinburgh, St. Andrews, and Aberdeen will be present.

3.45 p.m. - Garden party in the Zoological Park. Charabancs will leave Waterloo Place at 3.30. Return journey can be made at any time by tram-car from Park gates.

8.30 to 1 a.m. Palais de Danse, Fountainbridge. Reception by the President, and Dance.

Wednesday, July 6

10 a.m. - Medical Chemistry Classroom, Medical Buildings, The University. Joint Meeting with the Biochemical Society. Subject of discussion: "The Physiological and Industrial Aspects of the Chemistry of Carbohydrates." Chairman, Professor G. Barger, F.R.S. Papers will be read by:—(1) Professor W. N. Haworth, D.Sc., Ph.D., "Structural Relationships in the Carbohydrate Group"; (2) Professor A. R. Ling, M.Sc., F.I.C., "Recent Advances in our Knowledge of the

Polysaccharides"; (3) C. G. Lambie, Esq., M.B., Ch.B., F.R.C.P.E., "The Intermediary Metabolism of Carbohydrates"; (4) C. J. Fox, Esq., Ph.D., and L. Hall, Esq., Ph.D. (Cross and Bevan Laboratories), "Cellulose from the Industrial Standpoint."

10 a.m. - Midwifery Classroom, Medical Buildings, The University. Meeting of The Chemical Engineering Group. Chairman, F. Heron Rogers, Esq., M.I.Mech.E., M.I.Chem.E. Paper will be read by J. L. A. Macdonald, Esq., D.S.O., D.Sc., "Some Aspects of the Manufacture of Fibrous Cellulose." By kind permission of William Harrison, Esq., LL.B., Chairman of The Inveresk Paper Company, Limited, and associated Companies, a section of the film showing the activities of these Companies will be exhibited. This section shows "The Production of Esparto Paper from the Raw Material to the Finished Product." Discussion.

2.15 p.m. - University Chemistry Department, King's Buildings. (1) Lecture by Professor J. Read, University of St. Andrews, on "Natural Sources of Energy in Australia."; (2) Visit to University Chemical Laboratories. Charabancs will leave Waterloo Place at 2 p.m., returning from King's Buildings at 3.45 p.m.

2.15 p.m. - Visit to Edinburgh Corporation Gas Works, Granton. Charabancs will leave Waterloo Place at 2 p.m., returning from Granton at 3.45 p.m.

4 p.m. - Reception by invitation of The University Court in the Upper Library Hall, Old University Buildings.

7.15 for 7.30 p.m. - The North British Station Hotel. Annual Dinner of the Society. (Tickets, 12s. 6d. exclusive of wines.)

Thursday, July 7

10 a.m. - Medical Chemistry Classroom, Medical Buildings, The University. Lecture by the Society's Medallist, Lieut.-Colonel G. P. Pollitt, D.S.O., on "The Development of the Synthetic Nitrogen Industry in Great Britain."

11 a.m. - Midwifery Classroom, Medical Buildings, The University. Lecture by Monsieur Ernest Fournet, Pasteur Institute, Paris, on "Chemo-therapy in Relation to Tropical Diseases."

11 a.m.—Medical Chemistry Classroom, Medical Buildings, The University. Coal Cleaning Conference. To be held under the Joint Auspices of the Society of Chemical Industry (Fuel Section), the Institution of Gas Engineers, and the Coke Oven Managers' Association. Chairman, C. H. Lander, Esq., D.Sc. Papers will be read by:—(1) Dr. W. R. Chapman and Professor R. V. Wheeler, D.Sc., F.R.S., "Comparison of Processes for Cleaning Coal"; (2) Walter Guider, Esq., "Froth Flotation applied to a Baum Washer"; (3) F. S. Sinnatt, Esq., M.B.E., M.Sc., F.I.C., "A Consideration of Certain Problems encountered in the Preparation of Coal for the Market"; (4) C. W. H. Holmes, Esq., M.Met., "Notes on the Cleaning of Coal with Special Reference to Pneumatic Separation."

2.15 p.m.—Coal Cleaning Conference (*continued*).

2.45 p.m.—Visit to the Paper Mills of Messrs. James Brown & Co., Ltd., Penicuik. Charabancs will leave Waterloo Place at 2.15 p.m., returning from Penicuik at 5 p.m.

2.45 p.m. Visit to Castle Mills, Edinburgh, the works of The North British Rubber Co., Ltd. Charabancs will leave Waterloo Place at 2.30 p.m., returning from Castle Mills at 4.45 p.m.

p.m. City Chambers, Edinburgh. Reception by the Lord Provost and Magistrates of the City of Edinburgh.

Friday, July 8

Excursions:—(1) Whole-day excursion to Melrose, Abbotsford, Dryburgh, and Peebles. Tickets, including lunch and tea, 15s. Charabancs leave Waterloo Place at 10 a.m. (2) Afternoon excursion to Forth Bridge and Inchcolm. This excursion is limited to 90. Tickets, including tea, 6s. Charabancs leave Waterloo Place at 2 p.m. (3) Visit to Refinery of Messrs. Scottish Oils, Ltd., Grangemouth. Charabancs leave Waterloo Place at 2 p.m., returning from Grangemouth at 5.30 p.m. Evening: If a sufficient number of members apply for tickets (8s. each), a dance will be arranged for 8.30 to 1 a.m. Conducted tours of Old Edinburgh will be arranged on Thursday and Friday.

Saturday, July 9

The following excursions will be arranged if a sufficient number of members apply for tickets:—(1) Gleneagles Golf Course. Tickets 10s., including green fees. (2) St. Andrews (including visit to Chemical Laboratories of the University). Railway fare, 5s. 6d.

NOTICES

APPLICATIONS FOR TICKETS

Applications for tickets should be sent at the earliest possible date to The Honorary Secretary of the Edinburgh and East of Scotland Section, Dr. W. T. H. Williamson, 13, George Square, Edinburgh. Forms for this purpose will be issued to members in a few days. The application must

in every case be accompanied by the appropriate remittance for tickets and fares.

Members are kindly requested not to apply for tickets to any works if they are interested in a competitive business.

Members are entitled to bring guests to any of the Meetings except the Annual Business Meeting of the Society, to be held on July 5 at 10 a.m. In the case of the luncheon by invitation of The Edinburgh and East of Scotland Section, a member of the Society of Chemical Industry may bring only one guest.

The Local Committee will endeavour to meet all requirements, but accommodation at some of the functions is strictly limited, and tickets for these will be allotted in order of application.

Ticket-holders are specially asked to bear in mind that at functions for which tickets are issued **these tickets must be produced on admission.**

HEADQUARTERS IN EDINBURGH

The Office of the Society during the Meetings will be in The North British Station Hotel, Princes Street, Edinburgh, and members are requested to attend there on their arrival to register their names and receive their tickets for the various functions.

Members may have their letters sent to them "C/o The Society of Chemical Industry" at the office address given above.

REDUCED RAILWAY FARES

The Railway Companies of Great Britain (except the Metropolitan, the Metropolitan District, and London Electric Railway Companies) have agreed to issue tickets at the ordinary single fare and one third (minimum fare, 1s.) for the double journey to persons travelling to Edinburgh to attend the Meetings. Tickets will be available from Saturday, July 2, to Saturday, July 9, and will be obtainable at the time of booking on **production of a Voucher which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.**

It is urgently requested that all persons going by rail to Edinburgh for the Meetings will take advantage of this concession. Members travelling to Edinburgh on more than one occasion during the Meetings may obtain the reduced fare for each journey, and such members are requested to apply for as many vouchers as they can possibly use.

ACCOMMODATION

No bedrooms are now available in The North British Station Hotel. A list of other hotels was published in CHEMISTRY AND INDUSTRY for February 4, 1927 (p. 105).

Single-room accommodation for both men and women is still available in The University Hostels. Immediate application for such should be made to Dr. W. T. H. Williamson (address as above).

The Women Students' Common Room in the Medical Buildings of the University will be reserved as a **Reading and Writing Room** for the use of members.

ENQUIRIES

It is requested that all communications regarding the Annual Meeting should be sent to Dr. W. T. H. Williamson (as above).

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

MEMBERS ELECTED

May 13, 1927

- Bakes, William E., 64, Wellington Road, Charlton, London, S.E.7. Research Chemist.
- Bilton, Percy, Rock Cottage, Cottage Lane, Ormskirk Oil Chemist.
- Borden, Edmund G., c/o Henry L. Doherty & Co., 60, Wall Street, New York, N.Y., U.S.A. Patent Attorney.
- Honig, Dr. Ing P., Sugar Experiment Station, Paseroean, Java, D.E.I. Director.
- Oldham, W. D., 148, Philips Park Road, Beswick, Manchester. Works Chemist.
- Robertson, Robert B., 116, West Regent Street, Glasgow, C.2. Commercial Manager.
- Robinson, Charles S., Nobel House, Stevenston, Ayrshire. Chemical Engineer.
- Shaw, Dr. W. S., Scientific Dept., United Planters' Association of Southern India, Nellakota Experimental Station, Devarshola P.O., Nilgins, India. Tea Scientific Officer.

CALENDAR OF FORTHCOMING EVENTS

- May 24. ROYAL PHOTOGRAPHIC SOCIETY, 35, Russell Square, W.C.1, at 7 p.m. *Scientific and Technical Group*. (1) "Inherent fog in photogravure and a method for its elimination," by H. Mills Cartwright and F. J. Tritton. (2) "Optical and photographic properties of a series of typical cyanine dyestuffs," by F. M. Hamer and O. Bloch.
- May 28. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, *Associates' and Students' Section*. The Mining Institute, Neville Hall, Newcastle-upon-Tyne, at 3 p.m. "Variable speed gears and their application for colliery purposes," by W. S. Armstrong. (Illustrated by lantern slides.)
- May 31. ROYAL PHOTOGRAPHIC SOCIETY, 35, Russell Square, W.C.1. "The development of chloro-bromide papers" and "The exposure of colour-screen plates," by E. A. Bierman.
- June 9. OPTICAL SOCIETY. *Ordinary Meeting*. Imperial College of Science and Technology, Imperial Institute Road, South Kensington, S.W., at 7.30 p.m.
- June 14 to 17. INSTITUTION OF ELECTRICAL ENGINEERS. Summer Meeting at North-Eastern Centre. Numerous visits to Works. Registration Office, The Central Station Hotel, Newcastle-upon-Tyne.
- June 15. ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY, Northampton Polytechnic Institute, 81, John Street, Clerkenwell, London, E.C.1., at 8.15 p.m. "Electrorefining of silver," by E. Downs.
- June 15. SOCIETY OF GLASS TECHNOLOGY. Meeting at Sheffield.
- June 17 & 18. ASSOCIATION OF ECONOMIC BIOLOGISTS. June Meeting, The South-Eastern Agricultural College, Wye.
- June 18. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. General Meeting, at 2.30 p.m.
- June 29. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2., at 4 p.m. Annual General Meeting.

SOCIETY OF GLASS TECHNOLOGY

The Tenth Annual General Meeting was held in Sheffield on April 27, the President, Mr. Walter Butterworth, Senior, M.A., in the chair.

Mr. W. Butterworth was re-elected President, and the following officers were elected:—Vice-Presidents: H. A. Bateson and W. J. Rees, B.Sc.Tech. Ordinary Members of Council: J. D. Cauwood, M.Sc., F. Graves Clark, Miss V. Dimpleby, M.Sc., G. V. Evers and W. W. Warren, A.M.I.C.E., A.M.I.E.E.

Hon. Treasurers: General, J. Connolly; American, F. C. Flint, B.S. Hon. Secretary: Prof. W. E. S. Turner, D.Sc. Auditors: C. S. Davey, D. Wood, F.S.A.A.

At the Ordinary General Meeting which followed, a discussion on furnace efficiency was inaugurated by Prof. W. E. S. Turner, in a paper entitled "A brief review of furnace developments."

Prof. Turner stated that his intention was to survey the present position of furnace practice in this country and abroad as the basis for considering possible lines of advancement in the future.

Dealing with the operation of pot furnaces in this country, data were given of numerous furnaces engaged upon various types of work, some of the observations dating back to 1916. It was evident from the figures that (a) a saving in fuel was obtained by the newer types of recuperative or regenerative furnaces; (b) heavy expense was incurred by the practice of founding only once a week; (c) the fuel consumption was greatly increased when the eye of the furnace had worn big. The efficiency of modern British pot furnaces compared favourably with those of Germany.

Among the improvements effected during the last few years in furnace design were (1) greater compactness; (2) better utilisation of waste heat; (3) the introduction of tangential burners; and (4) sillimanite sieges. The type of ware made, greatly affected the efficiency, while mutual consideration of the problem by masters and men of methods of working should result in greater output at less cost.

Passing to the consideration of tank furnaces, Prof. Turner gave data of numerous tanks working for hand operation, for semi-automatic bottle machines, for mixed automatic and semi-automatic machines, and for fully automatic machines. Very few data were available relative to Continental practice, but from figures quoted by H. Maurach in 1925 the results obtained in Germany were probably not as good as those reached in this country. Speaking generally, tank furnace practice on the Continent had not reached the British attainment, which was now equal to anything yet achieved in America.

The main sources of economy with a view to increasing efficiency were indicated. Among the problems which still required more thorough examination were:—

- (a) Design of ports. End ports in some cases appeared to give longer life to tank blocks;
- (b) Bridges, the form of the basin, and whether there should be one or two dog-houses;
- (c) Depth of the refining end of the tank, whether it should be less than at the melting end;
- (d) Utilisation of waste heat; and

(e) Increased insulation in various parts of the furnace, crown, side walls, &c.

In conclusion, Prof. Turner referred to a suggestion made by Mr. B. P. Dudding that it would be a good thing to see how far it was possible by a national exchange of information to develop furnace operation to a fuller stage. The Department of Glass Technology of Sheffield University had recognised the importance of the problem, and several series of systematic measurements had already been carried out by members of the staff, at the request of some manufacturers. Work on these lines had been carried out in Germany since 1920, when an institution was set up to study the problems of furnaces and fuel in the glass industry. Similar systematic furnace measurements were needed in this country, since the sound lines for real progress must rest on measured data.

THE INSTITUTE OF METALS

Sir Henry A. Miers, F.R.S., delivered the seventeenth annual May Lecture before the Institute of Metals, at Storey's Gate, Westminster, S.W.1, on Wednesday, May 11.

He recalled in the address experiments made 20 years ago by himself and Miss Isaac, which seemed at that time to show that when a solution is cooled below its saturation temperature it passes into a "metastable" state in which crystals can only be produced by introducing a fragment of the dissolved substance or of one isomorphous with it, and that at a lower temperature it passes into a "labile" state in which crystals may appear spontaneously. Later investigations have shown that in the metastable state crystallisation can also be produced by shock.

The author, however, considers that his experiments record the normal behaviour of crystallising liquids and that crystallisation only takes place with some degree of supersaturation or undercooling. In his experiments there was always a sudden outburst of crystal growth at a definite temperature.

Little importance is ascribed to undercooling by most geologists in their speculations concerning the crystallisation of molten magmas, but to many metallurgists it is a very important factor. The structure of alloys is in many cases attributed to a suspended crystallisation of this nature; not only as they solidify from the molten state, but also during the crystalline changes which take place in the solid alloy with change of temperature, for example, in steel and in magnetic alloys.

ROYAL SOCIETY

At the Royal Society *Conversazione*, held on May 11, some interesting applications of ultra-violet radiation to chemical analysis were shown by A. A. King. The contamination of crystals of mercuric chloride by crystals of mercurous chloride and vice versa was rendered plainly visible by exposure of the crystals to ultra-violet radiation, when the mercuric salt exhibited a blue fluorescence, while the mercurous salt appeared orange. Stages in the purification of the impure salt could be readily followed by the change of colour of the fluorescence.

The use of ultra-violet radiation enables quantities of arsenic as small as 0.00001 milligram to be detected and estimated quantitatively. The Gutzeit method is used for the preparation of a mercury-arsenic stain upon filter paper sensitised with pure mercuric chloride. In ultra-violet radiation unchanged mercuric chloride fluoresces blue, whilst the mercury-arsenic stain stands out as a black disc. This contrast is used to detect arsenic stains which are quite invisible in ordinary light.

The presence of impurities in water is made plainly visible by transmission of ultra-violet radiation through the water. Even the purest conductivity water, under these conditions, scatters a small amount of fluorescent radiation.

The metallography of solid mercury and dilute amalgams of tin was demonstrated by Dr. W. Rosenhain and A. J. Murphy. The samples shown were prepared by solidification in liquid air or carbon dioxide snow, and etching in an aqueous solution of hydrochloric acid (freezing point -86° C.). During manipulation and examination the metal or alloy is maintained solid by immersion in liquid air, or carbon dioxide snow and acetone. Condensation of moisture on the specimen and microscope objective is prevented by enclosing the specimen and lens in a chamber through which passes a stream of cooled, dried air. Samples of iron, manganese and chromium containing impurities which were detectable only spectrographically, and silicon and beryllium of purity 99.95% and 99.8% respectively were exhibited by the National Physical Laboratory.

Sir Robert Hadfield exhibited a number of samples of manganese, non-corrodible, heat-resisting and non-scaling steels, including the non-corrodible steel possessing a tensile strength of 45–50 tons per square inch which is being used in the restoration of St. Paul's Cathedral, replacing the original wrought iron tie bars used by Wren.

A beautiful new type of electric discharge discovered by Dr. Irving Langmuir was exhibited by the British Thomson-Houston Co., Ltd. The usual type of mauve-coloured discharge is produced in a hot cathode discharge tube containing argon. Tungsten vapour is liberated into the gas from the cathode employed. If after the tube has been in operation for a little while the discharge is momentarily interrupted, a cloud of blue luminescence is seen to leave the cathode, and a yellow colour develops on the outside of the discharge, which now becomes extremely sensitive to a magnetic field, incandescent particles of tungsten being precipitated from the discharge and travelling across the discharge when a magnet is brought near the tube. The device has obvious possibilities as an advertising device, and we anticipate its advent on our streets after the manner of use of the familiar Neon tubes.

A form of thermostat employing the phenomenon of the loss of magnetic properties by magnetic materials over certain temperature ranges was exhibited by F. J. Campbell Allen and A. E. Salisbury.

A method of measuring the vacuum in electric lamps, due to P. Selényi, was shown by the General Electric Co. The residual gas in a vacuum lamp is ionised by the discharge between the ends of the lamp filament. The resulting conductivity of the gas increases the capacity

of the condenser formed by the filament and the exterior surface of the glass bulb. This capacity forms part of a circuit maintained in oscillation by a Neon lamp, and the amount of residual gas is indicated by the frequency of the oscillations.

The same firm demonstrated some new applications of gas-filled photoelectric cells, designed by Dr. N. R. Campbell. The novel feature of these demonstrations is that voltages higher than those required to pass a spark discharge through the cell are employed. Under these conditions the discharge is ordinarily unstable, but can be stabilised by a thermionic current limiter connected in series with the cell. The current is then intermittent, and the frequency of intermittence depends upon the intensity of the light incident upon the cell. Changes of this frequency serve to determine the intensity of illumination. The device finds application in the transmission of pictures by radio-telegraphy and in the measurement of feeble illuminations such as that due to stars etc. In the former case an initial frequency of about 5000 is used, whilst in the latter the initial frequency is about 1 per sec., and changes are made audible in a loud speaker.

Sir Robert Robertson exhibited a large rock salt prism of length of face $5\frac{1}{2}$ inches and height $4\frac{3}{4}$ inches made at the Government Laboratory from a nearly perfect piece of rock salt. The refracting angle of the prism is $60^{\circ} 0' 49.5''$.

CORRESPONDENCE THE LIFE OF FABRICS

SIR,—Mr. C. M. Whittaker takes exception (*CHEMISTRY AND INDUSTRY*, May 6, 1927, p. 425) to an assumption that the average life of laundered fabrics is five years, contained in a statement on page 41 of the pamphlet "Co-operative Industrial Research."

This very approximate estimate was reached after taking into account the varied types of articles sent to laundries. It was also connected with the frequency with which these articles are washed. It is obviously difficult to obtain any exact basis for calculation, but if an average of between 50 and 100 washes is assumed, then a period of five years corresponds to a mean rate between 10 and 20 washes per annum.

Of all the types of articles sent to a laundry, sheets and collars form but two sections out of many; although the life of collars is less than five years, the life of sheets certainly approaches and often exceeds that period; and the life of many articles greatly exceeds it. Hence the not unreasonable value of five years, taken as an average life, and affording some means of estimating the value, to the public, of any change in the average duration of existence of its linen.

It happens, however, that the point as to whether the average life is five years or less, does not greatly affect the value of the estimate made. It is stated that "if the average life of these fabrics is five years, the annual depreciation is of the order of £2,000,000. If, as a result of the adoption by these launderers of the improved methods suggested by the Association, the life of the fabrics is lengthened by no more than 5%, the customers will effect a saving of nearly £100,000 annually." The object of this is to show the magnitude

of the economy which is possible. Clearly, if, as Mr. Whittaker thinks, the average life is shorter than that stated, the annual depreciation is greater, and, consequently, the possible annual economy is still greater than the figure which is mentioned.

Yours faithfully,

R. G. PARKER,

Director of Research,

British Launderers' Research Association

THE COMMERCIAL POSITION OF ETHYLENE GLYCOL

SIR.—I have read with interest interspersed with surprise two communications concerning the manufacture and uses of ethylene glycol that appeared in recent numbers of *Seifensieder Zeitung* (53 (1926), 595 and 818). According to Grossman's article, the first cited, there is doubt in Germany respecting the commercial success of the manufacture of ethylene glycol in the United States; and in the note next referred to, "X" says that "it is necessary to warn against hopes that ethylene glycol can fully and completely take the place of glycerol," and that, in the explosives industry, "ethylene glycol will never be able to displace glycerol." Since these and other statements of Grossmann and of his anonymous colleague may have given rise to incorrect conclusions in the minds of the readers of their letters, I will present an accurate description of the technologic status of ethylene glycol in the United States.

The investigational work that has eventuated in the present activities of the Carbide and Carbon Chemicals Corporation, the manufacturer of ethylene glycol ("prestone") and of other derivatives of the olefine gases (e.g., diethyl sulfate, ethylene dichloride, isopropyl alcohol, and ethylene chlorhydrin), was begun at Mellon Institute in 1914 by Dr. G. O. Curme, jr., whose brilliant research achievements during particularly the following six years constitute a series of very notable contributions to industrial chemistry. Dr. Curme and his co-workers, the late Dr. H. R. Curme, Mr. E. W. Reid, and Dr. C. O. Young, have described some of the general results of their studies in a group of papers (*Chem. and Met. Eng.*, 25, (1921), 907—909, 957—959, 999—1000, 1049—1050 and 1091—1092). After passing through various experimental stages of gradually increasing size and efficiency, the processes of making ethylene glycol and other related compounds were first operated successfully on the commercial scale in the summer of 1925.

Ethylene glycol has therefore been manufactured commercially for almost two years by the Carbide and Carbon Chemicals Corporation, which is a unit of the Union Carbide and Carbon Corporation, 30, East 42nd Street, New York, N.Y. The production of ethylene glycol at this Corporation's South Charleston, West Virginia, plant was more than 5 million lb. in 1926, and there is every indication that the total output of the chemical in 1927 will be much greater than that. It is evident from these facts alone that the manufacture of ethylene glycol has already taken a definite place in American chemical industry.

The researches conducted at Mellon Institute supplemented by extensive practical experience make it clear that ethylene glycol is not a mere substitute for glycerol, but is actually superior to glycerol in many of its com-

mercial applications. For example, as an "anti-freeze," ethylene glycol will depress the freezing-point of water approximately 20% more than an equivalent quantity of glycerol.

It will interest European explosives specialists to learn that every large explosives manufacturer in the United States is now using ethylene glycol in dynamite. Ethylene glycol may readily be nitrated and its inclusion in dynamite gives a freeze-resistant ("anti-freeze") product, without diminution of sensitivity, which is not the case with polymerised glycerol, used hitherto for the same purpose. For further information, the reader is referred to an article on glycol dinitrate, by Mr. W. H. Rinkenback, of the Bureau of Mines, which will appear in *Chemical and Metallurgical Engineering*.

Because of the nature of the process of manufacturing ethylene glycol, its price does not follow the glycerol market. The Carbide and Carbon Chemicals Corporation has set the price at about 30 cents a lb. for spot quantities; this price has not varied during the whole of the past year, whereas the cost of c.p. glycerol has ranged from 25 cents to 35 cents a lb. It is understood that large consumers buying ethylene glycol on a contract basis have secured prices considerably lower than 30 cents a lb.

I know that the American producer of ethylene glycol has no intention of competing directly with glycerol manufacturers. The Carbide and Carbon Chemicals Corporation takes the view that both ethylene glycol and glycerol have their specific uses. Rather than attempt to capture the greater part of the glycerol market, this Corporation has announced that it will accept only that portion of the business that wants a superior article at a stable price. After this point has been reached, the officers say, the Corporation's manufacturing activities will be directed toward the production of other compounds such as ethylene glycol mono-ethyl ether ("cellosolve"), which has already reached an important position as a solvent in the manufacture of lacquers.

I am, Sir, etc.

EDWARD R. WEIDLEIN, *Director*,
Mellon Institute of Industrial Research,
University of Pittsburgh
Pittsburgh, Pa., U.S.A.

PERSONAL AND OTHER ITEMS

Sir Joseph Thomson has been elected Honorary Professor of Natural Philosophy, and Sir Ernest Rutherford Professor of Natural Philosophy of the Royal Institution.

Dr. H. W. Dudley, of the National Institute for Medical Research, has recently been appointed by the Committee of the Biochemical Society to represent it on the Federal Council of Pure and Applied Chemistry in succession to Prof. J. C. Drummond.

On May 17 the Lord Chancellor, Viscount Cave, unveiled at Oxford, armorial windows in the Ashmolean Museum commemorating distinguished Oxford men of science of the seventeenth century, including Sir Christopher Wren and Dr. Plot, Oxford's first professor of chemistry.

Dr. E. K. Rideal and Prof. J. C. Drummond have accepted an invitation to take part in the advanced

courses and in the daily conferences arranged by the Institute of Chemistry of the American Chemical Society.

Dr. C. S. Myers, F.R.S., the director of the National Institute of Industrial Psychology, has received the honorary degree of D.Sc. on the occasion of the commemoration of Founder's Day at Manchester University.

Sir Josiah Stamp will deliver the Rede Lecture at Cambridge on June 8, his subject being "On stimulus in the economic life."

Dr. M. O. Forster, F.R.S., has returned to England from India on holiday.

Mr. L. W. Bristowe has been elected Master of the Armourers' and Brasiers' Company, and Mr. T. E. L. Oakley Master of the Woolmen's Company.

Sir Samuel Hardman Lever and Sir Alexander Gibb have been elected directors of the Dunlop Rubber Company.

Mr. John Parke Jackson has been appointed as an additional member of the board of the Salt Union, Ltd. Mr. Jackson has been connected with the Union for 27 years, and occupies the positions of head of the Coastwise and Continental Sales Department and foreign representative.

Dr. R. H. Pickard, F.R.S., has been elected to the Senate of London University.

Mr. J. E. Purvis has been reappointed University lecturer in chemistry and physics at Cambridge.

Mr. J. Y. Macdonald, B.A., of University College, London, has been appointed to a lectureship in the chemistry department, United College of St. Salvator and St. Leonard, University of St. Andrews.

The directors of Sensible Heat Distillation, Ltd., are offering a scholarship of £250 a year to the Imperial College of Science, South Kensington, for the study of matters concerning the investigation of primary oils from British bituminous coals under Prof. W. A. Bone, in the Department of Fuel Technology.

Lady Ramsay has made a gift of chemical apparatus to the Wycombe Royal Grammar School from the laboratory of the late Sir William Ramsay.

Mr. J. E. Spurr has resigned from the editorship of the *Engineering and Mining Journal*.

The North of England Gas Managers' Association celebrated its Jubilee on May 5 at Newcastle.

Under the name of "Sociedad Quimica Mexicana," a new chemical society has been founded in Mexico, with Dr. F. Lisci as first president. The objects of the society are wide, including an employment bureau, means for helping members financially, and a library and laboratory, as well as the advancement of chemistry and the publication of an official organ, the *Revista Quimica*.

The late Mr. T. Whitaker, a director of the Bradford Dyers' Association, left £22,599.

The late Mr. R. Hendry, J.P., formerly head dyer and analytical chemist at the Kilncraigs works of Messrs. Patons & Baldwins, left £15,909.

From Germany the following deaths are announced : Dr. R. Hagenbach-Burckhardt, formerly general director of the Höchst Farbwerke ; Prof. Tschermak, emeritus professor of mineralogy at Vienna University ; Prof. W. Filehne, who was one of the first to introduce antipyrin and pyramidon to medical use.

Reported Negotiations between British and German Chemical Industries

The Board of Imperial Chemical Industries, Ltd., has issued the following statement :—" The statements which have appeared in the press regarding alleged negotiations between Imperial Chemical Industries, Limited, and the Interessen Gemeinschaft Farbenindustrie, A.G., purporting to give the scope of such negotiations and intimating that an agreement is likely to be reached within a short time, are inaccurate and entirely unauthorised. The facts are that only preliminary discussions have taken place between the two companies, with a view to examining the question of closer co-operation in the various fields of chemical activity."

Research Scholarships tenable in Germany

Five Research Scholarships tenable at certain German universities will be available for the year 1927-28. Each student will receive free maintenance (or an equivalent allowance) and free tuition. Candidates should be male graduates of an English University, and should send their applications to the Anglo-German Academic Board through the Vice-Chancellor of their University ; graduates of Oxford, Cambridge, and London through the Head of their College. Applications must include a statement of the research work the candidate proposes to undertake, and must be submitted not later than May 21.

Safety First Order

The Home Secretary announces that he has provisionally approved the issue of an order requiring the institution of special safety arrangements in the chief accident producing industries, including, amongst others, blast-furnaces for smelting iron ore, various types of engineering works and large foundries. Opportunity is given for those interested to submit observations on the proposals.

Third Census of Production (1924). Matches

The following data are extracted from the " Preliminary Reports " of the Third Census of Production (1924) :—During the year 1924 the production of matches in Great Britain amounted in value to £4,371,000, and in 1907 the output of the United Kingdom as a whole was valued at £855,000, the large increase in value being due to a great extent to the Excise Duty which has been imposed since 1907. The rate of duty in 1924 was 5s. per 10,000 matches in boxes not exceeding 80 matches and one third less for matches in excess of 80 in the box. During the fiscal year ended March 31, 1925, the quantity of matches retained for home consumption was 7,078,000 standard gross. The quantities retained for use and consumption in the United Kingdom were less in the first quarter of 1925 than in the first quarter of 1924 by 78,000 standard gross. There were thus 7,156,000 standard gross retained for consumption in the year 1924. The exports on drawback and clearances free of duty amounted in

the year 1924 to 342,000 standard gross. Thus the quantities charged to duty and cleared free of duty in the year 1924 were, roundly, 7,498,000 standard gross, including 119,000 standard gross in Northern Ireland. In 1925 the quantities presented for clearance in Great Britain were approximately 500,000 standard gross less than in 1924, and in 1926 a further decrease of approximately 500,000 standard gross was recorded. In 1924 the total production of matches in Great Britain was 7,230,000 standard gross ; exports amounted to 302,000 standard gross, and imports entered for home consumption totalled 5,611,000 standard gross. The total quantity of matches, therefore, available in the United Kingdom for consumption during the year 1924 may be estimated at about 126,600 millions. The net output of the factories and workshops in Great Britain covered by the above statement amounted in value to £3,448,000, which represents a net output per person of £675, compared with £96 in 1907. The number of persons employed in the industry during 1924 was 5108, against 4256 in 1907. The total capacity of engines engaged in the industry in 1924 was returned as 5413 h.p., compared with 1591 h.p. in 1907. The capacity of the electric generators at factories in 1924 was 2348 kw., and in 1907 116 kw.

Canadian Exports of Pulp and Paper

Canada's exports of pulp and paper for 1926 were valued at \$173,491,635, as compared with a total of \$154,555,951 for the year 1925, an increase for the past twelve months, according to the Dominion Bureau of Statistics, of \$18,935,684, or over 12 per cent. Exports of wood-pulp were valued at \$52,077,122 and exports of paper at \$121,414,513, an increase over 1925 of \$4,145,217 in the value of pulp exports and of \$11,790,467 in the value of paper exports. The greatest increase was shown in the exports of newsprint, which rose from 1,401,655 tons, valued at \$98,945,337, in 1925, to 1,731,986 tons, valued at \$114,090,595, in 1926, an increase of 330,331 tons in quantity and \$15,145,258 in value. Exports of pulpwood were somewhat smaller in 1926, the total being 1,391,738 cords, valued at \$14,067,030, as compared with 1,423,502 cords, valued at \$14,168,935, in 1925.

Carbide in Tasmania

At the end of February, 1925, the Tasmanian Government foreclosed on Carbide & Electro-Products, Ltd., at Electrona. It then adopted the Soderberg continuous electrode process, which was stated to effect a saving of 33% in electrode consumption and an increased production of 15%. At a later date a British company was given an option for the purchase of the works. In March last the Australian Commonwealth Carbide Co. was registered in London with a nominal capital of £200,000 to purchase the works. A sum of £52,000 has been received by the Government on account, the total purchase price being £140,000. Although this means a loss of £14,000, the Government will benefit later as the company will purchase a large amount of hydro-electric power and will start production on a large scale.

Second International Conference on Bituminous Coal

A second international Conference on Bituminous Coal will be held at the Carnegie Institute of Technology

in November, 1928, according to an announcement by Dr. Thomas S. Baker, president of the institution. The statement is contained in the recently issued volume of proceedings of the first conference held from November 15 to 18, 1926. President Baker states that the second conference will be planned to uncover whatever new information is made available during the coming two years regarding various problems in the use of soft coal.

The first conference was called by President Baker for the purpose of finding new uses for bituminous coal, and especially to discuss the problem of liquefying coal to supplement the petroleum oil supply of the world. More than 1700 delegates, including representatives of thirteen different countries, attended. The speakers included Dr. Friedrich Bergius and Prof. Franz Fischer, who have successfully liquefied coal; General Georges Patart and Jean Bing, of France; Dr. C. H. Lander, Geoffrey M. Gill, Harald Nielsen, and Dr. R. Lessing, of England; and several other well-known foreign scientists in addition to a long list of prominent American engineers and men of affairs and science.

Sulphuric Acid in the U.S.A.

During the period July-December, 1926, fertiliser manufacturers in the United States produced 810,326 tons of sulphuric acid and consumed 972,806 tons in the manufacture of 1,805,691 tons of acid phosphates containing 30,613,000 units (of 20 lb.) of available phosphoric acid. The output of acid by fertiliser makers equalled 83.3% of the consumption. Compared with the same period of 1925, production of acid phosphates during the last half of 1926 declined by 11.8%, sales decreasing by 11.1%.

Paint and Varnish in the U.S.A.

From an official census of the U.S. paint and varnish industry during the second half of 1926, it appears that 581 establishments (a gain of 5%) reported production. Firms grinding white lead and zinc oxide decreased in number, but there was no important change in the number of firms grinding other paints. Production of paste paints was 212,536,900 lb., a decrease of 5%, and the output of ready-mixed paints decreased by 4%, whilst sales of paints and varnishes decreased in about the same proportion. 372 firms (a gain of 25%) reported the manufacture of varnishes other than pyroxylin products, which were produced by 138 firms, an increase of 60%. Pyroxylin products constituted 15.7% of the total output of varnishes, and sales of pyroxylin products, in proportion to production, declined by 3% below the 1925 figures, though doubled in volume.

Franco-German Potash in the U.S.A.

The French and German potash syndicates have agreed to amalgamate their selling organisations in America and carry them on jointly from May 1. There are other agreements in regard to the rationing of the exports of the two industries and to price regulations. The amalgamation of the organisations has now been made the occasion of a suit by the United States Government under the anti-trust regulations for the vetoing of the formation of the sales organisation, and for prohibiting "any similar agreement or any increase of the price of potash in the United States." The

opinion is, however, finding frequent expression that this action has been taken solely to secure a price reduction, or a guarantee of a stable price for French and German potash.

Synthetic Methanol in France

The Etablissements Kuhlman is erecting a plant at Loos, near Lille, for the manufacture of synthetic methanol by the Patart process. It is expected to begin production at the rate of 1½ tons daily in June.

Italian Dyestuffs Agreement

In order to expand production, obviate competition and control sales, the Fabbriche Italiane Materie Coloranti Bonelli has made an agreement covering production and sales of intermediates and dyes with the group—said to be the Società Italiana del Gas of Turin—which controls the S.I.P.E. Cengio, the Italica and Schiapparelli concerns, and the Unione Produttori e Consumatori Materie Coloranti Artificiali, the last-named company being responsible for the distribution of reparatory dyestuffs. The capital of the Bonelli concern has been increased from 45 to 60 million lire.

Proposed Chemical Merger in Italy

It is announced in the *Financial Times* that negotiations are in progress between the Società Italiana del Gas, the Società Italiana Prodotti Esplosivi and the Società Materie Coloranti Bonelli, which are amongst the principal chemical producing companies in Italy, with the object of arriving at co-ordination of manufacture through inter-locking capital arrangements. The scheme is approved by the Government, and it is expected that the Treasury will contribute financial support in order to make the venture successful and so render Italy independent of foreign markets.

Bergius Process

The A.G. für Kohlenveredlung und Kohlenverflüssigung has been founded, with a capital of 5 million marks, to exploit the Bergius process for the liquefaction of coal. The licensees of the Bergius patents in Germany are the I.-G. Farbenindustrie and the Gesellschaft für Teerverwertung.

German Tetralin Combine

The Ges. für Teerverwertung, the Rütgerswerke A.-G., the Klockner Werke A.-G., the J. D. Riedel A.-G. and other German companies have combined to form a new company, the Deutsche Hydrierwerke A.-G. (Dehydrog), with a capital of 4 million marks, with the object of controlling the manufacture of tetralin. The process and plant used has been purchased from the J. D. Riedel A.-G.

Notes from Germany

It is stated that sales of German potash are increasing. Sales in January amounted to 190,000 tons, as against 94,000 tons in January, 1926, and 165,000 tons in January, 1925, and, according to present results, February should be a record month.

Noddack and Berg, speaking recently before the German Chemical Society, announced that they have prepared 1 mg. of rhenium as the oxide from 10 kg. of gadolinite. The oxide sublimes at 300° C. and gives a colourless solution in hydrochloric acid. The sulphide is grey in colour, and is insoluble in ammonium sulphide.

REVIEWS

PHOTOSYNTHESIS. By H. A. SPOEHR. American Chemical Society Monograph Series. Pp. 393. New York: Chemical Catalog Co., Inc., 1926. Price \$6.50.

One of the most fascinating problems has always been the mechanism whereby the living green plant achieves the photosynthesis of its complex products from carbon dioxide, water, and soluble nitrates. The subject is discussed in this volume by an author who has done much to advance our knowledge in this field. As he himself says, much of the speculation regarding the manner in which the green plant utilises solar energy has, unfortunately, not been restrained by a knowledge of certain facts concerning the process. Whilst it is true that our knowledge of many phases is still incomplete, yet there are certain well-established facts which cannot be disregarded in any consideration of the problem. The author has, in the main, emphasised the results of experimental investigation rather than the conclusions drawn from observations in the field, or by empirical methods.

The subject is dealt with in seven chapters, of which the first contains an historical introduction and a general discussion of the conversion of solar energy by means of green plants and trees. The second chapter deals with the nature of photosynthesis as determined by observations of gaseous interchange and the formation of organic matter. The two next chapters are devoted to the products of photosynthesis, and the methods of measuring photosynthetic activity. Then follow chapters on the chemistry of photosynthesis and its energy relations, and in the last is found an account of chlorophyll and the chloroplasts.

Under each heading is given a full account of the observed facts, together with very complete references to the literature, this being a distinguishing feature.

The book as a whole is admirably put together, and the author has undoubtedly achieved a great success in presenting the subject in a manner that is both interesting and learned. The value of the book is increased by the constructive criticism which the author gives from time to time, and the impression gained on reading it is one of keen satisfaction at finding the subject so well treated from both a broad and a deep outlook. E. C. C. BALY

A LABORATORY BOOK OF ELEMENTARY ORGANIC CHEMISTRY. By ALEXANDER LOWY, Ph.D., and WILMER E. BALDWIN, M.S. Pp. ix + 182. New York: John Wiley & Sons, Inc.; London: Chapman and Hall, Ltd., 1926. Price 15s.

This book represents the laboratory part of the elementary course of organic chemistry of the University of Pittsburgh, and is intended to teach the technique of organic chemistry, which it does in rather an elaborate and detailed fashion. The book is large in size, the pages measuring 11 in. \times 8 $\frac{3}{4}$ in., and is therefore not very convenient for carrying about. The book commences with much good advice regarding general methods of work, and, if precept were sufficient for the purpose, should turn out a generation of almost perfect chemists. After some notes relating to fires and accidents in the laboratory, methods of purification of organic compounds, determination of physical constants, and methods of

distillation are dealt with. Some 36 other experiments then follow, covering the field of elementary organic chemistry. The special features of the book are (1) the profusion of illustrations of chemical apparatus of all sorts, both simple and large scale, relating to experiments in hand; (2) the very precise character of the instructions given for the various experiments; and (3) the addition after each chapter of a questionnaire to be written up by the student to show that he has properly understood the experiment he has been engaged on. These pages are perforated so that they can be torn out and handed to the demonstrators. Accepting the point of view from which the book is written, it must be described as remarkably complete, but I am inclined to think that the results obtained by a somewhat simpler method would be equally satisfactory. T. S. PATTERSON

FERTILISERS—THEIR SOURCES, MANUFACTURE AND USES. By HERBERT CAVE. Pitman's Common Commodities and Industries Series. Pp. xii + 116. London: Sir Isaac Pitman & Sons, Ltd. 1926. Price 3s.

The author is to be congratulated on the production of "a little book presenting a general non-technical account of the sources, manufacture and uses of fertilisers."

Greatest attention is paid to the three principal groups, the phosphatic, nitrogenous and potassic fertilisers, and the functions of each group are briefly reviewed. The chapter on mineral phosphates deals with the development of the supply, and clearly indicates the influence which the exploitation of the North African phosphate has had upon the American industry. It is unfortunate that only a passing reference is made to the results which have been obtained by using the finely-ground raw mineral phosphates.

The statement, on page 27, dealing with the effect of calcium fluoride on the citric solubility of open-hearth fluorspar basic slag is rather misleading, as the calcium fluoride is present in combination with tricalcium phosphate as the mineral *apatite*.

The Chilean nitrate industry and the production of by-product sulphate of ammonia are discussed, and a concise account of the manufacture of atmospheric nitrogen compounds is given.

Various substances, such as bone manures, guanos, meat and fish meals, farmyard manure and lime are mentioned in Chapter 7, but the statement made on page 80 that only the "free lime is of any use for removing acidity in the soil" is one which is scarcely warranted. A chapter is also included on the utilisation of fertilisers in agriculture, which should prove useful to those readers unfamiliar with farm practice, a commendable feature being the exhortation to farmers and others to conduct trials to ascertain the requirements of the particular soil under observation.

A useful chapter, entitled "Commercial information," deals with the valuation of fertilisers and the Fertilisers and Feeding Stuffs Act and its proposed amendment.

The appendices, dealing with the world production of various fertilisers, form a valuable compilation, and will prove useful for reference purposes.

D. N. McARTHUR

PARLIAMENTARY NEWS

Dutiable Chemicals (Postal Packets)

In a written answer to Mr. Meller, Mr. McNeill stated that there was a general prohibition against the importation of dutiable articles by the letter and sample posts. Articles thus imported were liable to forfeiture. *Bona fide* trade samples of dutiable chemicals were, however, in practice admitted on payment of duty and a fine. It was not possible to waive the prohibition in favour of chemicals and admit them free of any charge. There was no objection to the importation of dutiable chemicals by the parcel post, provided that the contents of the parcel were duly declared by the senders, and chemicals so imported were delivered on payment of duty.—April 26.

Sugar-Beet Industry

In reply to Commander Bellairs, Mr. Guinness stated that the area under sugar beet in France and Great Britain in 1926 was 513,000 acres and 129,000 acres respectively. The 1927 figure for Great Britain would, it was estimated, exceed 200,000 acres. The financial assistance given to the British beet industry was laid down in the British Sugar (Subsidy) Act, 1925, and as regarded sugar, amounts during the period of the highest rate of subsidy ending September 30, 1928, to 19s. 6d. per cwt. on sugar exceeding 98° polarisation. Excise duty amounting to 7s. 4d. per cwt. was paid by the home manufacturer as compared with the Customs duty on foreign sugars of 11s. 8d. per cwt. As far as he knew, no direct subsidy was enjoyed by the old-established sugar industry in France. The French producer was, however, protected by a Customs duty on foreign sugars which amounted at the current rate of exchange to 6s. 10d. per cwt. on sugar exceeding 98%₀. Colonial and indigenous sugars did not pay this duty. On all sugars in France of home, colonial or foreign origin an internal consumption tax of 10s. 3d. per cwt. was levied.—April 26.

Coal Slack (Oil Production)

The Duchess of Atholl informed Mr. Hurd that the National Physical Laboratory does not conduct tests of coal slack. Experiments had shown that it was possible to produce oil from British coals comparable in efficiency with imported oil, but no pronouncement could be made as yet as to the possibility of doing this under commercial conditions. Further information on this question could be had from recent reports of the Department of Scientific and Industrial Research, notably Fuel Research Technical Paper No. 17, and the Annual Report of the Fuel Research Board for 1925.—May 3.

Coal (Oil Extraction)

In reply to Mr. Thurtle, the Duchess of Atholl stated that there were several processes of extracting oil from coal. Tar, from which oils were produced, was obtained commercially in gasworks etc. in Germany as in this country. Low-temperature carbonisation processes had long been employed for the extraction of oil from brown coal in Germany, and oil was now being produced on a commercial scale in Germany by the hydrogenation of brown coal.—May 5.

Dyestuffs (Imports)

Sir P. Cunliffe-Lister informed Lieut.-Commander Kenworthy that the value of finished dyestuffs obtained

from coal tar, imported into the United Kingdom in 1926, was £876,529, and in the first three months of 1927, £290,308.—May 10.

COMPANY NEWS

BRITISH DRUG HOUSES, LTD.

The annual general meeting was held on May 4, Mr. C. A. Hill, Ph.C., B.Sc. (chairman and managing director), presiding. In moving the adoption of the report and accounts for the year to December 31, 1926 (cf. CHEM. AND IND., May 6, 1927, p. 426), the chairman said that the profit of £16,864 had been arrived at after charging every expense, including certain items quite properly charged to revenue, and yet of an extraordinary or non-recurrent nature, which it was anticipated that 1926 would have to bear. In February, 1926, he estimated that the profit available, after making due provision for prior charges, would suffice to pay a dividend of not less than 7½% on the ordinary shares, and anticipated that in the near future the ordinary shares would be on a 10% basis. He still had that same confidence and the same anticipation, but in February, 1926, he did not anticipate the serious and protracted industrial crises which followed and which so materially affected last year's results. The effect of the coal dispute on the company's profit and loss was that of a double pull—on the credit side, the general curtailment of business, the restricted buying power of the public and the effect upon industrial conditions generally, combined to depress the profits; whilst on the debit side, the company had to contend with the increased cost of home-manufactured goods and increased working expenses, due to the high cost of transport and the exorbitant prices paid for imported coal. Despite such increases in costs of manufacture and distribution, prices of the company's own products were not advanced. Had the conditions during last year been normal, the accounts would have shown a very different result. Reference was made to the work of the B.D.H. laboratories, and the striking discoveries in the domain of biochemistry and the research on vitamins. An encouraging increase in the turnover for the first three months of 1927 was recorded.

CASSEL CYANIDE CO., LTD.

An interim dividend has been declared of 3d. per share, less income tax at 4s. in £, payable on June 2.

BRITISH CELANESE, LTD.

In order to acquaint shareholders with the progress and prospects of the company and to give time for proper consideration of the problems arising out of the situation which has arisen with regard to future control, a detailed statement of the balances of the profit and loss accounts month by month has been issued. It shows net profits for the first three months of 1927 of £35,288, £46,354, and £61,831 respectively, against corresponding losses for 1926 of £18,884, £19,719, and £1564. There is an increasing demand for the company's products at satisfactory prices. In March, 1927, for the first time a profit was made in all departments without exception, and the total net profit for the month is considerably higher than any other in the company's history, not excluding the months of ficti-

tiously high profit just before the institution of the silk duties. The extensions to the spinning plant will, when completed, increase the company's spinning capacity by about 25%.

BENZOL AND BY-PRODUCTS CO., LTD.

Presiding at the seventh annual general meeting, held on April 19, Sir A. Henry McMahon, chairman, said that the business of the company was primarily that of a colliery, and subject to all the vicissitudes of the coal trade. The general strike and the coal dispute had caused a total stoppage of all colliery working for seven months, of which five fell within the year under review. During 1925-26 their production of coal, coke, sulphate of ammonia, pitch and benzol was in almost every case little more than half that of the previous year, which in itself was one of the worst ever experienced in the history of the coal trade.

The report for the year ended September 30, 1926, states that after making full allowance for depreciation and all other expenses, there was a loss of £12,097, compared with a loss of £9470 for 1925. With £12,111 brought forward, and £1060 written back from income tax reserve, £13,171 is available. After deducting the loss and transferring £521 to sinking fund account, there remained a profit of £553, which will be carried forward. Since the settlement of the coal dispute, trade had considerably improved, and the directors felt able to recommend payment on April 1, 1927, of one year's arrears of dividend of 6% on the preference shares. This left one year's 6% cumulative preference dividend still in arrears.

One or two facts connected with the business which seemed to justify confidence in the future were, firstly, that operations were restarted after the enforced stoppage with the advantage of thoroughly overhauled, and, where necessary, renewed machinery and plant; secondly, it was hoped that the new mining shaft in place of the previous upcast shaft would be working by June next, which would greatly increase the output of a superior grade of coal with reduced overall getting costs. Thirdly, the acquisition of the Upholland Colliery and its 35 coke ovens was proving the success anticipated.

ALLEN-LIVERSIDGE AND CO., LTD.

A dividend has been declared on the preference shares at the rate of 6½% per annum (less tax) for the six months ended April 30, 1927.

AMALGAMATED ANTHRACITE COLLIERIES, LTD.

At a meeting of shareholders on May 10, the scheme for amalgamating with the United Anthracite Collieries, Ltd., and other companies, was unanimously approved. The scheme provides for the nominal capital of the company being increased to £5,000,000 and for the issue of bonus shares in the proportion of one for every ten shares held. United Anthracite Collieries and its subsidiary companies and also the subsidiary companies of Amalgamated Anthracite Collieries are to be wound up. With the liquidation of these concerns the Amalgamated Anthracite Collieries would take over the entire assets and would primarily be an operating company with the direct management of its twenty-four collieries and its various selling organisations.

BURT, BOULTON, AND HAYWOOD, LTD.

It is proposed to increase the authorised capital of this company to £720,000 by the creation of 100,000 new ordinary shares of £1 each, and to issue in the immediate future 50,000 of the new shares.

BRYANT AND MAY, LTD.

The net profit for the year ended March, 1927, was £387,212, compared with £334,920 for 1926. After placing £106,202 to reserve and allocating £20,000 to employees' funds, £72,415 was carried forward (against £74,452), after paying a dividend of 12½% (same).

VICKERS, LTD.

The report for 1926 shows a net profit of £562,284, compared with £120,973 for 1925, which, having regard to the dislocation of trade resulting from the coal dispute, the directors do not consider unsatisfactory. Preference dividends absorbed £418,190, leaving £144,093, which, with £190,775 brought forward, makes a total of £334,868. The directors do not recommend the payment of any dividend on the ordinary shares, but propose to place £200,000 to reserve fund, carrying forward £134,868. The board has secured the services of Mr. G. G. Sim as secretary. Mr. F. C. Yapp has been appointed a member of the Armaments and Shipbuilding Management Board, and Mr. Alex. Williamson and Mr. George Vickers have been elected special directors, located at Sheffield. Mr. Vincent C. Vickers resigned his seat on the board last June.

NON-INFLAMMABLE FILM CO., LTD.

The statutory meeting was held on April 28, 1927, at Herbert E. Blain, C.B.E., chairman, presiding. He said it would be recognised that the Company made available a British non-inflammable film where flammable film supplied from abroad had had a practical monopoly; that it should widen enormously the possibilities of the use of the film in many directions where its former flammable defects proved a barrier; that it should materially cheapen splinterless glass for many useful purposes; and that acetate of cellulose plays a very important part in the manufacture of artificial silk, besides a number of other uses to which it might be applied which were only beginning to be studied. Summarising the company's progress to date, the chairman said that alterations had been made to existing works and additional equipment had been provided, so that the regular output of film might be commenced. Having regard to the rumours which had been circulated that the company could not turn out satisfactory film at its works, the company had made a film wholly at its works, and had had it printed by one of the largest picture-producing companies in this country, which had no interest whatever in the company. They reported as follows: "We have found the results quite satisfactory. The material perforates perfectly, the stock appears to be of very high grade in regard to wearing quality and strength, and its photographic quality appears to be fully equal to standard." The Board was pursuing a very careful policy, and was planning carefully the foundations for what it hoped would be a noteworthy new industry.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial. Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid. £5 -£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P. Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Sal ammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s. £4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5 -£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined). £10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic, Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.

Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor. 9d.—10d. 16½ Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carbolic.—Crystals.—8½d.—9d. per lb. Crude 60's, 2s. 6d. 2s. 8d. per gal.
 Acid Cresylic, 99/100. 2s. 8d.—2s. 9d. per gal. Steady, 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality. 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 8d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole. 90%, 1s. 9d. to 2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol.—2s.—2s. 4d. per gal. Pure, 3s. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naptha.—Crude, 8½d.—9d. per gal., according to quality.
 Solvent 90/160, 1s. 10d.—1s. 11d. per gal. Solvent 95/160, 1s. 6d.—1s. 7d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis. d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.
 Aniline Salts.—7d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4d. per lb.
 m-Cresol 98/100%.—2s. 8½d. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—2s. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene. 66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 3d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylydine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%. £39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d. 2s. 6d. per lb.
 Acid, Benzoic B.P.—2s. 2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum 1s. 3d. per oz.; 500 oz. lots.—1s. per oz.
 Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 7d. per lb. Less 5%. Advancing.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed. 8s. 3d. per lb.
 Acid, Salicylic. B.P. 1s. 3½d. 1s. 4d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric. 1s. 3½d. per lb. Less 5%. Firm market.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d. 1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24 per ton, Powder £25 per ton. carr. paid any station in Great Britain in ton lots.
 Bromides.—Ammonium.—2s. 4d.—2s. 5d. per lb. Potassium.—1s. 11d.—2s. per lb. Sodium.—2s. 2d.—2s. 3d. per lb. All spot.
 Calcium Lactate.—1s. 3½d.—1s. 4½d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ether meth.—1s. 1d.—1s. 11½d., per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—22s. per cwt., 112 lb. lots.
 Magnesium Carbonate.—Light Commercial £31 per ton net.
 Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½% in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 10s. 6d.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig. 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonat.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin.—3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar) 97s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferriyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17. 5d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb. Very limited inquiry.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.
 Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
 Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
 Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
 Sulphonol.—7s. 6d. per lb.
 Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.
 Thymol, Puriss.—11s.—12s. per lb., according to quantity.
 Natural.—14s. 9d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
 Aubepine (*ex Anethole*).—10s. 6d. per lb.
 Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb.
 Amyl Salicylate.—3s. per lb.
 Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
 Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb.
 Benzyl Alcohol free from Chlorine.—2s. per lb.
 Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.
 Cinnamic Aldehyde.—Natural, 17s. per lb.
 Coumarin.—10s. 6d. per lb.
 Citronellol.—14s. 6d. per lb.
 Citral.—8s. 3d. per lb.
 Ethyl Cinnamate.—10s. per lb.
 Ethyl Phthalate.—2s. 9d. per lb.
 Eugenol. 9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.
 Methyl Anthranilate.—8s. 6d. per lb.
 Methyl Benzoate.—4s. 6d. per lb.
 Musk Ketone.—35s. per lb.
 Musk Xylol.—8s. 6d. per lb.
 Nerolin.—3s. 9d. per lb.
 Phenyl Ethyl Acetate.—12s. per lb.
 Phenyl Ethyl Alcohol.—9s. 9d. per lb.
 Rhodinol.—30s. per lb. Safrol.—1s. 6d. per lb. Terpineol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—14s. 3d. per lb.
 Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Puro, 1s. 10d. per lb. Clove, pure.—6s. per lb.
 Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 9d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 16s. 9d. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 9th, 1927, are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C.2, on May 26th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I. Applications

Holmes & Co., Ltd., Cooper, and Henshaw. Drying gases. 1,691. May 2.
 I.-G. Farbenind. Manufacture of catalysts. 12,124.
 1,240. May 5 and 6. (Ger., 27.11.26.)

Power Specialty Co. Fractionating-tower. 11,871. May 3. (U.S., 5.5.26.)

Rowlands. Separating and filtering apparatus. 11,897. May 4.

I.—Complete Specifications

2070 (1926). Simon-Carves, Ltd., and Robinson. *See* 11. 3812 (1926). Crushing or grinding machines. (247,943.)
 5192 (1926). Moore and Campbell. Electrically-heated kilns. (270,035.)
 8674 (1926). Allgem. Kommerzges. A.-G., and Mannesmann. Separating the solid and liquid constituents of a material. (270,066.)
 13,539 (1926). Godel. Recovery of gases and vapours by solid absorbents. (270,099.)
 14,775 (1926). Haddan (Oliver Continuous Filter Co.). Pulp thickeners or filters. (270,108.)
 17,255 (1926). Fulton. Heating and drying apparatus. (270,122.)
 25,281 (1926). Visco-Engineering Co., Ltd., and Smith. Air and gas filtering apparatus. (270,157.)
 25,738 (1926). I.-G. Farbenind. Manufacture of linings for vessels to resist acids. (260,575.)
 25,993 (1926). Smith and Hayes. Pulverising-mill. (270,159.)
 *10,920—1 (1927). Urbain Corp. Separation of gases from mixtures. (270,286—7.)
 *11,050 (1927). I.-G. Farbenind. Producing solid materials in a state of fine dispersion. (270,293.)
 *11,600 (1927). Kocour. Determining the strength of solutions. (270,338.)
 *11,607 (1927). Theisen. Apparatus for treating gases with liquids. (270,340.)

II.—Applications

Arnold (Standard Development Co.). Treatment of heavy hydrocarbons. 11,746. May 2.
 Bervoets. Manufacture of mineral oils from peat etc. 11,744. May 2. (Holland, 1.5.26.)
 Bloxam (Allgem. Ges. f. Chem. Ind.). Treatment of gasoline etc. 12,323. May 7.
 Bookey and Lyne. Apparatus for manufacturing gas. 11,750. May 3.
 Callender, King, and Mardles. 11,936. *See* XII.
 Coppée et Cie. Coke oven. 11,700. May 2. (Belg., 4.9.26.)
 Donner. Converting hydrocarbons. 11,803. May 3.
 I.-G. Farbenind. Pulverulent fuels for internal-combustion engines. 11,658—7. May 2. (Ger., 7.5.26.) Conversion of hydrocarbons. 11,658. May 2. (Ger., 7.5.26.) Production of hydrocarbons. 11,659. May 2. (Ger., 10.5.26.)
 McLeod. Oil-cracking process. 11,632. May 2.

II.—Complete Specifications

1661 (1926). Urbain. Manufacture of absorbent carbon. (269,961.)
 1814 (1926). Kohlenveredlung Ges. Cracking or fixing of the illuminating constituents of coal gas. (246,490.)
 2070 (1926). Simon-Carves, Ltd., and Robinson. Draining and concentrating coal and other slimes. (269,967.)
 2562 (1926). Patart. *See* XX.
 2889 (1926). Allgem. Kommerzges. A.-G., and Mannesmann. Treatment of peat. (269,993.)
 2894 and 3039 (1926). Fairweather (Urbana Coke Corp.). Coking coal. (269,994 and 270,003.)
 3152 (1926). Power-Gas Corp., and Rambush. Production of water gas and coal gas. (270,009.)
 19,725 (1926). I.-G. Farbenind. Removal of benzol from gases containing the same. (257,906.)
 *10,178 (1927). Bataafsche Petroleum Maatsch. Treatment of cracking or sludge residues. (270,274.)

*10,475 (1927). Tormin. Carbonising fuels. (270,277.)
 *11,347-8 (1927). I.-G. Farbenind. Conversion of hydrocarbons of high boiling-point into compounds of lower boiling-point. (270,313-4.)

*11,378 (1927). Lederer. Producing gas. (270,318.)

*11,744 (1927). Bervoets. Manufacture of mineral oils from peat, lignite, etc. (270,349.)

III.—Applications

Bünge. Separation of neutral constituents from crude tar etc. 11,806. May 3. (Ger., 21.3.27.)

Bünge and Macura. Working up crude tar. 11,962. May 4. (Ger., 8.2.27.)

III.—Complete Specification

10,725 (1926). I.-G. Farbenind. See II.

IV.—Applications

British Celanese, Ltd., Bader, and Green. 11,644. See XX.
 British Dyestuffs Corp., Ltd., Bainbridge, and Payman. Intermediate compounds for preparation of dyestuffs. 11,709. May 2.

Carpmael (I.-G. Farbenind.). Reducing aromatic amino compounds. 11,994. May 4. Manufacture of dyestuffs. 11,995, 11,997. May 4.

Chem. Fabr. van der Grinten, and Grinten. Manufacture of diazo-types. 11,846. May 3.

I.-G. Farbenind. Manufacture of azo dyestuffs. 11,844-5. May 3. (Ger., 31.5.26.) Manufacture of naphthalene etc. condensation products. 12,10.3. May 5. (Ger., 30.6.26.)

Imray (I.-G. Farbenind.). Manufacture of dyestuffs. 12,125-6. May 5.

Johnson (I.-G. Farbenind.). Manufacturing reduction products of vat dyestuffs etc. 11,990. May 4.

Soc. Chem. Ind. in Basle. Dyestuffs. 11,728. May 2. (Switz., 30.4.26.)

Yava Works, Ltd. (Arnot). 11,706. See XX.

IV.—Complete Specifications

32,759 (1925). I.-G. Farbenind. Manufacture of condensation products of the anthraquinone series. (245,165.)

32,911 (1925). Chem. Works (Sandoz). Production of azo dyestuffs for dyeing cellulose esters. (245,758.)

2258 (1926). Fabr. Chem. Production, and Kraus. Manufacture of sulphurised derivatives of phenols and naphthols and their application as mordants. (269,970.)

2259 (1926). Fabr. Chem. Production, and Kraus. Manufacture of sulphurised derivatives of naphthols. (269,971.)

*11,288 (1927). I.-G. Farbenind. Manufacture of mordant dyestuffs. (270,308.)

*11,728 (1927). Soc. Chem. Ind. in Basle. Manufacture of dyestuffs. (270,348.)

*11,844 (1927). I.-G. Farbenind. Manufacture of azo dyestuffs. (270,351.)

*11,845 (1927). I.-G. Farbenind. Manufacture of a yellow azo dyestuff. (270,352.)

V.—Applications

British Celanese, Ltd., and Ellis. Treatment of materials containing cellulose derivatives. 11,645. May 2.

I.-G. Farbenind. Protecting materials from moth. 12,104. May 5. (Ger., 13.7.26.)

Nobel Industries, Ltd. (Du Pont de Nemours & Co.). Cellulose ester compositions. 12,128. May 5.

Robins. Non-explosive films of cellulose etc. 11,898. May 4.

Singer and Wolff. 11,738. See XIII.

V.—Complete Specifications

9534 (1926). Soie de Chatillon Soc. Anon. Italiana. Maturation of alkali cellulose. (250,617.)

23,092 (1926). Peace and Carnegie. Treating jute fibres. (270,150.)

*11,589 (1926). Laucks, Inc. Cellulose fibre product. (270,335.)

VI.—Application

Hunt. Open bleaching-kiers. 12,268. May 7.

VI.—Complete Specifications

29 (1926). Brandwood (Holton). Treatment of yarns with fluids. (269,954.)

1631 (1926). Brit. Celanese, Ltd., Ellis, and Goldthorpe. Dyeing, printing, or stencilling of acetyl cellulose. (269,960.)

2258 (1926). Fabr. Chem. Production, and Kraus. See IV. 9802 (1926). Silver Springs Bleaching and Dyeing Co., and Hall. Dyeing furs, hairs, skins, and feathers. (270,075.)

15,433 (1926). Darco Sales Corp. Treating dye effluents. (262,382.)

*11,287 (1927). I.-G. Farbenind. Dyeing. (270,307.)

*11,499 (1927). I.-G. Farbenind. Dyeing with vat dyestuffs. (270,328.)

*11,567-8 (1927). I.-G. Farbenind. Treatment of fibrous materials and textiles. (270,333.4.)

VII.—Applications

Carpmael (I.-G. Farbenind.). Concentration of acetic acid solutions. 11,996. May 4.

Coles. 12,278. See XIII.

Meyerhofer. Production of soluble hydrates. 11,837. May 3. (Ger., 19.5.26.)

Odling and Street. Treatment of slag for production of aluminium sulphate etc. 11,970. May 4.

Pease. Manufacture of potassium phosphate etc. 11,725. May 2.

Permutit A.-G. Production of chromyl chloride. 11,805. May 3. (Ger., 5.5.26.)

VII.—Complete Specifications

29,982 (1925). Ashcroft. See X.

5497 (1926). Johnson (I.-G. Farbenind.). Manufacture of active silica. (270,040.)

21,086 (1926). Philips' Gloeilampenfabr. Separating hafnium and zirconium. (258,243.)

223 (1927). Norsk Hydro-Elektrisk Kvælstofakt. Production of granulated dust-free nitrate of lime (264,480.)

895 (1927). Aluminum Co. of America. Production of sodium aluminate. (264,823.)

986 (1927). Meyer and Meyer. Manufacture of copper sulphate. (264,510.)

VIII.—Applications

Bennion, Clarke, and Plant. Ovens for firing pottery. 12,152. May 6.

Brenley. Manufacture of refractory materials. 12,067. May 5.

U.S. Metals Refining Co. Magnesite refractories. 12,149. May 6. (U.S., 8.6.26.)

IX.—Applications

Marks (Polysius). Manufacture of aluminous cement. 12,211. May 6.

Pardoe. Making bricks etc. 11,908. May 4.

IX.—Complete Specifications

2376 (1926). Ros and Barton. Colouring cements, plasters, etc. (269,974.)

2403 (1926). Westrum. Manufacture of bituminous concrete. (269,975.)

3284 (1926). Cuse. Making concrete. (270,013.)

X.—Applications

Bury and Walker. Recovery of lead and zinc. 11,832. May 3.

Cernik and Stoces. Plants for extracting gold from sea water. 11,804. May 3.

Eaton. Chromium plating machines. 11,648 and 11,650. May 2. Electrodeposition of chromium. 11,649. May 2.

Fletcher. Surface hardening of metal. 11,856. May 3.

Kelly. Alloys. 11,637. May 2.

Metropolitan-Vickers Electrical Co. Ltd., and Sumpter. Surface hardening of metal. 11,858. May 3.

Morris Motors (1926), Ltd., Richardson, and Smart. Case hardening etc. iron etc. 11,954. May 4.
 Odling and Street. 11,970. See VII.
 Schiffer. Production of steel. 11,815. May 3.
 Webster. Acid-resisting alloy. 12,243. May 6.

X.—Complete Specifications

29,082 (1925). Ashcroft. Recovering constituents of metallic salts for use in treatment of ores etc. (269,749.)
 1498 (1926). Murakami. Shaft furnaces for reducing iron ores. (269,959.)
 8100 (1926). White (American Magnesium Corp.). Refining calcium and magnesium and their alloys. (270,060.)
 21,057 (1926). Metropolitan-Vickers Electrical Co., Ltd. Chromium plating. (258,242.)
 21,349 (1926). Zahn & Co., and Wickop. Extracting chromium ore. (270,143.)
 *31,533 (1926). Krupp A.-G. Making chromium steel free from annealing brittleness. (270,247.)
 *11,172 (1927). Rey. Ferrous metals. (270,298.)

XI.—Applications

Automatic and Electric Furnaces, Ltd., and Coleman. Electric furnaces. 11,987. May 4.
 British Thomson-Houston Co., Ltd. Treating filaments. 12,078. May 6. (U.S., 10.5.26.)
 Eaton. 11,648—50. See X.
 Edison Swan Electric Co., Ltd., and Webster. Electric cells. 11,868. May 3.
 Pettinelli. Electric storage batteries. 11,847. May 3.

XI.—Complete Specifications

2430 (1926). Koningsveld, and Ever Ready Co. (Great Britain), Ltd. Dry batteries. (269,977.)
 2782 (1926). Deodato. Electric accumulators. (256,569.)
 5192 (1926). Moore and Campbell. Electrically-heated kilns. (270,035.)
 13,936 (1926). Croud (Jessup and Moore Paper Co.). Electrolytic cells. (270,104.)

XII.—Applications

British Thomson-Houston Co., Ltd. Oleaginous compositions. 11,964. May 4. (U.S., 4.5.26.)
 Callender, King, and Mardles. Oils. 11,936. May 4.
 I.-G. Farbenind. Production of soap-like preparations. 12,295. May 7. (Ger., 15.5.26.)
 Martens and Watty. 11,711. See XIX.

XII.—Complete Specifications

28,988 (1925). Eichengrün. Dissolving or extracting fats, oils, etc. (243,030.)
 2652 (1926). Powling. Recovery of fats, oils, etc. (269,985.)
 5292 (1926). McKenna (Dunman and Legg). See XVII.
 12,695 (1926). Leroudier. See XIX.
 15,736 (1926). Allbright-Nell Co. Rendering fat and oil containing solids of animal origin. (253,952.)
 26,544 (1926). Schou. Manufacturing soap. (266,291.)
 *11,114 (1927). Tillisch. Vitaminising fats. (270,296.)

XIII.—Applications

Coles. Production of litharge. 12,278. May 7.
 I.-G. Farbenind. Production of colour lakes. 12,294. May 7. (Ger., 10.5.26.)
 Singer and Wolff. Production of cellulose lacquers etc. 11,738. May 2.

XIII.—Complete Specification

2363 (1926). Griffiths Bros. & Co., London, Ltd., and Britton. Manufacture of resin-like bodies. (269,973.)

XIV.—Application

Rubber Latex Research Corp. Stabilised latex. 12,326. May 7. (U.S., 3.1.27.)

XV.—Applications

Beer. Production of tanning-agents. 11,739. May 2.
 Chem. Fabr. Worms. Production of tanning-agents. 11,739. May 2.

XV.—Complete Specifications

*9633 (1927). Röhm & Haas A.-G. Tanning with metallic salts and salts of silicic acid. (270,267.)
 *10,523 (1927). Technicolor Motion Picture Corp. See XXI.

XVII.—Applications

Rak. Batteries for continuous diffusion of sugar etc. 12,321. May 7.
 Treuhand Ges. Bartmann & Co. 12,183. See XIX.

XVII.—Complete Specification

5292 (1926). McKenna (Dunman and Legg). Extracting wax from filter-cake or residue of cane sugar manufacture. (270,036.)

XVIII.—Complete Specification

27,378 (1926). Weber. Manufacture of yeast. (264,795.)

XIX.—Applications

Martens and Watty. Manufacture of margarine. 11,711. May 2.
 Treuhand Ges. Bartmann & Co. Treatment of cereals. 11,660. May 2. (Ger., 6.5.26.) Treatment of materials containing starch. 12,183. May 6. (Ger., 17.5.26.)

XIX.—Complete Specifications

32,664 (1925). Nanji and Paton. Manufacture of pectin products. (269,952.)
 4569 (1926). Seligman. Sterilising and preserving liquids. (270,030.)
 7484 (1926). United Yeast Co., Ltd., Salmon, and Jackson. Preservation of liquid eggs. (270,052.)
 12,695 (1926). Leroudier. Manufacture of oleomargarine. (252,369.)
 *11,114 (1927). Tillisch. See XII.

XX.—Applications

Boedecker. Preparation of mono-ethyl ethers of proto-catechuic aldehyde. 12,189. May 6. (Ger., 24.1.27.)
 British Celanese, Ltd., Bader, and Green. Manufacture of organic compounds. 11,644. May 2.
 Carpmel (I.-G. Farbenind.). 11,994. See IV.
 Chem. Fabr. vorm. Schering. Manufacture of aminomethylmercaptosulphonic acid etc. 11,998. May 4. (Ger., 5.5.26.)
 Glover. Cancer toxin and antitoxin. 12,209. May 6.
 Macallum. Manufacture of diacetyl 3:3'-diamino-4:4'-dihydroxy-5:5'-diiodoarsenobenzene etc. 12,003. May 4.
 May & Baker, Ltd., and Stickings. Manufacture of arylarsinic acids. 11,864. May 3.
 Yava Works, Ltd. (Arnot). Preparation of condensation products from amines. 11,706. May 2.

XX.—Complete Specifications

27,355 (1925). Branco. Preparation of artificial medicinal waters. (269,660.)
 2560 (1926). Patart. Synthetic production of higher alcohols. (247,177.)
 2562 (1926). Patart. Method for simultaneously synthesising methanol and liquid hydrocarbons. (247,932.)
 11,987 (1926). Newbery, Paxon, and May & Baker, Ltd. Manufacture of unsymmetrical arylarseno-compounds. (270,091.)
 18,578 (1926). Dyk. Polymerised vinyl-chloride modification. (260,550.)
 *10,743 (1927). Raschig. Process for the production of chlorthymol. (270,283.)
 *11,603 (1927). Soc. of Chem. Ind. in Basle. Manufacture of derivatives of substituted quinoline carboxylic acids. (270,339.)

XXI.—Applications

I.-G. Farbenind. Protective layers for photographic films. 11,727. May 2. (Ger., 1.5.26.) Manufacture of photographic plates etc. 11,980. May 4. (Ger., 12.8.26.)
 Pereira. Photography. 12,333. May 7.

XXI.—Complete Specifications

*10,522 (1927). Technicolor Motion Picture Corp. Preparation of coloured reproductions by imbibition. (270,279.)

*10,523 (1927). Technicolor Motion Picture Corp. Hardening gelatin films and surfaces. (270,280.)

*11,727 (1927). I.-G. Farbenind. Protective layers for photographic films. (270,347.)

XXIII.—Complete Specifications

3233 (1926). Amos. Tanks and apparatus for aerating sewage etc. (270,012.)

15,433 (1926). Darco Sales Corp. *See* VI.

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Earthenware (Commercial Bureau, Australia House, Strand, W.C.2. Ref. No. 412). *Belgium*: Asbestos packing, metal packings and valves (478). *British India*: Steel (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *Brazil*: Artificial silk yarns (495). *Canada*: Iron and steel, metals (475). *Egypt*: Vegetable oils, chemicals (492). *Greece*: Coal tar (B.X. 3511). *Rumania*: Non-ferrous metals, tinplate,terne plates, black corrugated sheets (491). *South Africa*: Glass water containers (B.X. 3500); varnish, enamel (B.X. 3499); brass piping, brass and copper sheets (A.X. 1667). *United Kingdom*: Metal alloys (23060/27).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during March, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 606, of which 479 were from merchants or importers. To these should be added 10 cases outstanding on February 28, making a total for the month of 616. The total number of applications received during April was 624, of which 496 were from merchants or importers. To these should be added 26 cases outstanding on March 31, making a total for the month of 650. These were dealt with as follows:—**Granted**—560 (of which 527 were dealt with within 7 days of receipt); referred to British makers of similar products—56 (of which 49 were dealt with within 7 days of receipt); referred to Reparation Supplies available—5 (all dealt with within 2 days of receipt); outstanding on April 30, 1927—29. Of the total of 650 applications received 581, or 89%, were dealt with within 7 days of receipt.

British Standard Specifications

The British Engineering Standards Association has issued British Standard Specification No. 277—1927 for Ready Mixed Linseed Oil Paint (Oil Gloss), Zinc Oxide, and No 278—1927 for Ready Mixed Linseed Oil Paint (Oil Gloss), Tinted Paints (Zinc Oxide Base). They contain clauses regulating the composition, together with standard reception tests, for the purchase

of these materials, and appendices giving methods of carrying out the tests. These specifications have been prepared at the request of the paint manufacturers by a committee representative of both the buying and manufacturing interests, and as in the case of all British Standard Specifications, they will be reviewed as experience of their working or progress in the industry renders it necessary, and revised issues will be published from time to time. Amongst other specifications in hand which will be published as completed are the following:—Painting materials—red oxide of iron oil paste, Class 1 and 2, lead chromes, prussian blues, lithopone, lithopone oil paste, carbon black, mineral black, vegetable black, lamp black and gold size. Copies of the new specifications (Nos. 277 and 278—1927) may be obtained from the B.E.S.A. Publications Department, 28, Victoria Street, London, S.W.1, price 2s. 2d. each, post free.

Monel Metal

We learn that G. & J. Weir, Ltd., have formed a subsidiary company under the same name in Paris, with a capital of 1,000,000 francs, to market monel metal in France and its colonies and protectorates, Belgium, and Switzerland.

EDITORIAL

An Academy Portrait

We publish in this issue a reproduction of a portrait by Mr. T. C. Dugdale of our senior active chemist, Prof. H. E. Armstrong. We think he is our senior chemist as well, and he is perhaps our most active chemist, so our composite description is certainly well justified. Within the last few months he has attended numerous meetings, organised receptions and dinners, published a large and important book, written an interesting chapter on modern views of chemistry as part of a memorial volume dealing with Newton, and had his portrait painted for exhibition in the Royal Academy. His attendance at conversaziones and the opera is undiminished, and we believe that he spends his surplus time in cultivating his garden and in playing Schumann records on a singularly excellent gramophone. In conjunction with Mr. Barlow, who has also many years to his credit, he pursues his study of dodecahedral models which these two conjurors fit together to represent the complex organic compounds now engaging their attention. One such model has been included in Prof. Armstrong's portrait. It is, of course, possible to make a mental picture of the more or less impenetrable space which lies between the atomic nucleus and the outermost ring of electrons, to consider this volume as capable of close-packing, to endow its theoretical surfaces with faces, angles and corners, and to fit these imaginary faces together in a logical and geometrical system of three dimensions. To one who has abundant unsaturated affinities, a vivid imagination and still dexterous fingers, this is probably an agreeable diversion: to many of us it would be hard work. Whether the logical system devised by the professor is more rigid than the facts of organic chemistry require we do not know. If this is the case, so much the worse for the facts. We are amused to find that the professor has for thirty-seven years, to our knowledge, and possibly for many more years, been urging that solution in water is a matter of association rather than dissociation, and that during most of this period his rather solitary cry has made less noise than the numerous chemists who claimed that hydrochloric acid split up at once when introduced into water, and now the reviewer of his book claims that

Armstrong's view and the current view are so close that we have only to solve some simple problem of the nature of deciding whether soda-water is one word or two words connected by a syphon. When the ionists have decided whether the negative chloride radical is single or married or lives *à la carte*, then we shall know how much of the difference between them and Armstrong is merely a question of verbiage: all will be peace and the voice of the turtle will be heard in the land.

These questions of the structure of organic compounds and of the nature of salts in aqueous solution are of singular importance and difficulty. The evidence obtainable is not very abundant, and is by no means easy to interpret, and these are two good reasons why only few chemists spend much time discussing them. A close observer could find other reasons: chemistry is not merely an exact science like mathematics; it is also an art which, like making pastry or playing the piano, is not attainable by all. Some chemists are so clever with their fingers that they can perform feats in the laboratory beyond the powers of most of their contemporaries, and they very properly make use of their exceptional skill in synthesis and analysis rather than in speculation. Moreover, chemists have, we imagine, a method of making use of their theories, and the evidence for and against them, which is different from the methods of many other people. We think it was Sir William Pope who recently announced that to the chemist a theory was a tool rather than a creed. If we have wrongly attributed this paradox we offer our apologies, but in any event the statement expresses a truth. So long as the theory helps the chemist to understand, to prophesy, and to correlate hitherto isolated facts, he is satisfied with it, till some usurper rise, and he, too, mighty thoughtful, mighty wise, studies new lines, and other circles feigns. As speculations require no manual dexterity to discuss, and no profound knowledge to comprehend, they are dear to editors and also to that large body of amateurs who discover that many branches of chemistry cannot conveniently be acquired by an amateur. Chemistry is for the professional man, and it seems that even when the chemist is within measurable distance of his eightieth year he can still go on learning it and teaching it.

CHEMICAL FIRE EXTINGUISHERS*

By W. R. ORMANDY, D.Sc., F.I.C., M.I.Chem.E.

A very decided step in the history of civilisation dates from the time when men deliberately made use of fire, but though a useful servant, fire is a dangerous master, and the increased use of fire in all forms has led of necessity, with the advance of civilisation, to the adoption of means for fighting the uncontrolled action of fire.

It is interesting to glance at the losses arising from fire, as shown by the insurance statistics. In the United Kingdom fire loss during the period of ten years amounted to £80,595,000, this does not include the thousands of fires where the damage amounted to less than a thousand pounds per fire. In the last two years of the period under review, the losses were £12,878,000 and £14,616,000 respectively, amounts far in excess of any of the earlier totals during the same period. The loss of life amounted to 7,927, with additional thousands maimed and injured.

In America conditions are even worse. In the year 1925 it is estimated that over 14,000 persons were burned to death and 16,000 injured by fire in the United States. Of these, 80% were of the dependent class—that is, mothers, children, sick in hospitals, etc. The preliminary estimate of the fire loss in the United States for 1925 is over 570 million dollars—that is, over a thousand dollars a minute throughout the year. Over 60% of the fires takes place in homes, and it is interesting to follow the analyses of fire causes, as far as these are available. Carelessness with matches, cigars, cigarettes, etc. caused damage of over 30 millions; defective chimneys and flues, over 22 millions; accidents arising from stoves, flues, boilers and their pipes, over 21 millions; spontaneous combustion caused damage of over 17 millions, and sparks on roofs over 15 millions; carelessness with electrical appliances caused a loss of about 14½ million dollars, and nearly one half of all the electrical accidents arose from the use of the electric flat iron. The remainder were largely attributable to bad wiring. It is instructive to note that only 4% of the electrical losses arose in buildings which were wired according to the National Electric Code. These American statistics are taken from the paper by W. J. Rodgers, junr., read at the Sixth Annual Meeting of the Fire Chiefs of the Bethlehem Steel Corporation.

It may be of some interest to take a short backwards view over the progress of fire fighting in this country. At the time of the Great Fire of London (1666) the fire appliances then in existence consisted of brass-handled squirts and leather buckets. The squirt, having been filled by one man, was operated by another. It held about a gallon of water, and was very like an enlarged modern garden syringe.

The City of London was divided into four districts, and, according to the Act in 1667, each district was provided with two squirts and 800 leather buckets, together with a number of spades and pick-axes. Soon after this two rival engine-makers succeeded in perfecting a kind of fire engine, and one eventually made an engine capable of throwing a jet of water to a height

of 165 feet; this apparently put the other man out of business, for nothing more is heard of him. These engines, although on wheels, were usually placed on trucks with larger wheels, to get them more rapidly to the scene of the fire.

Owing to the slow progress made by fire appliances a "Fire Watch" or "Fire Brigade" was established in 1791, the work being for the most part undertaken by the insurance offices. Each company had its own engine and men, who wore an emblem of the offices on a badge displayed on their left arm. Their uniform consisted of a double-breasted jacket, knee-breeches and long boots, with an overcoat worn over the jacket.

In 1830 the insurance companies resolved to reorganise their forces by doing away with the separate establishments and combining the whole in one brigade. The London Fire Brigade (which to-day is known as the Metropolitan Fire Brigade) became an established fact in 1833. It was supported by ten of the insurance offices, who contributed to the expense of maintenance in accordance with the business they did. It existed in this manner for about 33 years, and although steam fire engines were introduced to them in 1835, it was almost at the end of their existence before they were adopted. In the early days of fire engines each office had its special "office" mark, which consisted of a plate of lead or other metal bearing their name or trade mark, which was placed on the front of the building of the insured person. Before the amalgamation of the various offices these plates were intended to decide which company's engine should attend in the event of a fire. It has been stated that in the earlier days a form had to be filled in and sent the nearest brigade, notifying them that their service were required.

The basic means employed for fire fighting are comparatively few in number. First, and most important, comes the use of water, which is regarded rather as a means for reducing the temperature at the source of the fire than as a means for the production of steam intended to extinguish the fire by preventing access of oxygen. In the second class are those bodies which are employed for the production of large bulks of preferably heavy vapours which smother the fire by preventing access of oxygen or by reducing the oxygen constituent of the gases, surrounding the fire to a point at which combustion is not readily carried on. A third means for fire fighting is the application of solid materials, such as sand, earth, or preferably bodies which give off non-inflammable gases when heated. The fourth and most modern means is that known as the Foam Method.

GROUP I

We will deal with these various groups one by one. In this short review it is intended only to deal with what may be called "portable" or "hand" means for fighting fires in their incipient stage. The various forms of what are known as "S and A" appliances (soda and acid) are among the best known and the most widely distributed. A solution of sodium bicarbonate is contained in a pressure-resisting vessel and sulphuric acid is contained in an internal vessel, which at desire can be caused to mix with the sodium bicar-

* Read at the meeting of the Chemical Engineering Group on May 6.

bonate solution, thus generating carbon dioxide, the pressure so produced serving to eject the liquid in a powerful stream. Such S and A appliances are made in 1- and 2-gal. sizes and up to a maximum of about 40 gals., in which case the containers are on wheels and can be handled by one or two men. These appliances must be considered as belonging to Class I, for, after all, the extinguishing medium remains the water, since the carbon dioxide contained in the liquid when it arrives at the fire is too small in quantity to be of any importance. Obviously such machines have to be made of a material which will resist sulphuric acid. For this purpose lead-lined vessels are almost entirely employed, and great care should be taken that the ratio of acid to alkali in the charges is as nearly theoretically correct as possible. Needless to say, such appliances are worse than useless for electrical fires, for the liquid, containing large quantities of sodium sulphate, is an excellent conductor of electricity. In any case, the results arising from the utilisation of a strong, even neutral, salt solution are sufficiently unpleasant under any conditions.

GROUP II

It would not be unreasonable to re-name Group II the "Carbon Tetrachloride Group" since, although other bodies are used to some extent, carbon tetrachloride is used in the overwhelming majority of cases. What is required is a material which shall produce from a given bulk of liquid the maximum quantity of a vapour which shall be heavy, non-combustible, and as stable to heat and the chemical conditions arising in a fire as possible. Having regard to the price, carbon tetrachloride has been found to fulfil the required conditions better than anything else, and hundreds of thousands, if not millions, of first-aid fire extinguishing appliances are in use all over the world making use of CCl_4 as their basic material.

For the most part, these appliances consist of a double-acting pump of about 1 quart capacity, the whole being so arranged that it will pump equally efficiently whether pointing downwards or upwards and will act until the entire contents are discharged. There is a considerable number of chlorinated carbon compounds which do not support combustion, but of them carbon tetrachloride is the most stable, and even in the presence of moisture less liable to form acid bodies deleterious to the metal of the container. The chemist is often astonished to find that in industrial processes chemicals are often required of a degree of purity even greater than he is accustomed to use in the laboratory. This is particularly true of carbon tetrachloride for use in fire-extinguishing appliances. The commercial product is always liable to contain carbon disulphide and traces of moisture, and both of these are immensely active in bringing about metallic corrosion. It is only by the use of CCl_4 of an extraordinary degree of purity that it is possible to get fire appliances filled with this product which after ten and fifteen years of inaction are found to be in perfect condition. Needless to remark, when the purchaser of such a fire appliance, after ejecting some of the carefully purified contents, fills up with tap water, the need not be astonished at the destruction which will inevitably arise.

The chemist will at once ask what happens to carbon

tetrachloride in contact with flames and carbonaceous or other material at a high temperature. This point has been very carefully studied both by A. H. Nuckolls, Chemical Engineer to the Underwriters' Laboratories, and by the Bureau of Mines, both of America. In the first place, since carbon tetrachloride freezes at a temperature which is very frequently reached in America, it is necessary there to add other bodies to lower the freezing point, and for this purpose up to 10% of chloroform is most frequently added. On the assumption that the depression of the freezing point follows the normal law, methyl alcohol would be expected to be a most efficient diluent, but in effect it turns out that the freezing point reduction caused by this material is only a fraction of that which would be expected, and one must assume, therefore, that methyl alcohol in solution in carbon tetrachloride is very heavily associated. The fact that chloroform has to be used as an anti-freeze material in cold countries is important in view of the discoveries of the investigators above referred to. It must be stated that both investigations were carried out in a manner which would represent the most dangerous conditions likely to arise in actual practice, such as a fire in a submarine, in a cellar, or a small room with no ventilation. It was proved in both cases that carbonyl chloride was produced in small quantities and chlorine only under exceptional circumstances, also in small quantities. Hydrochloric acid gas was invariably formed, but the quantity of chlorine and hydrogen chloride necessary to make themselves unpleasantly evident is very much less than that which forms a lethal dose. It would appear that chlorine is principally formed when red-hot iron comes in contact with the extinguishing fluid. The most dangerous ingredient is undoubtedly phosgene, and it is interesting to note that the quantities of this produced were very much greater when the carbon tetrachloride employed contained small quantities of carbon disulphide and/or chloroform, but that in no case, working with reasonably pure materials and under conditions which obtain in the majority of cases, was the production of these deleterious bodies in any way sufficient to justify the prohibition of use of what is undoubtedly one of the best fire extinguishing materials at present employed.

It may be of interest to note the method employed at the Underwriters' Laboratory for the detection and estimation of quantities of phosgene falling between 2 and 150 parts per million in the gases drawn off from the fire. For purposes of tests, gases were drawn through a solution of ammonia and the urea formed by the reaction, together with ammonium chloride, was extracted with amyl alcohol, in which ammonium chloride is insoluble; oxalic acid is then added and phosgene, if present, gives a crystalline precipitate of ammonium oxalate. For quantitative determination the fumes were drawn in known volume over granulated metallic antimony to remove chlorine and through a cold saturated solution of aniline. Under these conditions phosgene gives diphenylurea, insoluble under the conditions, which is simply washed, dried and weighed.

Attached to the report of the National Fire Protection Association on the "Behaviour of Carbon Tetrachloride"

under "Fire Conditions" is a table of the toxicities of air containing gases and vapours from fire extinguishers, together with the concentration at which these various bodies affect the eyes and throat.

In the summary and conclusions of the Bureau of Mines Report it is stated "It is not the intention of this paper to prescribe the use of carbon tetrachloride extinguishers which are excellent in stopping incipient fires, but rather to point out the danger which can occur with their application."

It is interesting to note that not only does purity of the carbon tetrachloride lead to immunity from corrosive action on the container, but it also tends toward the production of less noxious bodies in contact with flame and heated materials.

A very excellent fire extinguishing medium is methyl bromide, either alone or together with methyl chloride. It is, however, expensive, and owing to the low boiling point, very difficult to retain for any length of time in anything other than sealed vessels. Owing to the low boiling point, this material ejects itself under pressure from the vessel in which it is contained. Small glass tubes with capillary ends filled with methyl bromide are certainly wonderfully efficacious in the laboratory for the extinction of small fires arising from the breaking of flasks during the distillation of volatile inflammable liquids. The high price and the difficulties above mentioned are, however, likely to militate against the introduction of such bodies on any considerable scale.

GROUP III

It is obvious that the utilisation of solid materials, such as dried sand, is only possible under limited and special conditions. In the first place, it is obviously only possible where the fire is at a low level. Finely divided powders are certainly better than water to apply to petrol, paraffin and tar or inflammable liquids generally, unless the water supply is available in overwhelming quantities or can be used as steam in enclosed places. At one period dry powders contained in cases were recommended for fire extinguishing, and in 1916 the Government caused a Committee to report to them the result of "Experiments to test the value of dry powder fire extinguishers as compared with water and other first-aid appliances for extinguishing or effectively controlling fires such as are likely to be caused by bombs." The report of this Committee was handed in during April, 1916; their conclusions are certainly anything but favourable to the extinguishers tested.

Four different types of powder extinguishers were examined, and they were found to contain for the most part about 50% of sodium bicarbonate, the balance being finely ground chalk or other equally cheap filler. The analyses show that if the whole of the carbonic acid available on heating were given off suddenly in the fire, one cubic foot of gas would be formed for each pound of powder used. As a pound of water gives 1600 times its volume of steam, the relative value for fire extinction purposes is easily seen. It was pointed out that the cost of the contents of such powder fire extinguishers was about twopence. The report is a strong condemnation of the type of powder fire extinguisher, at one time largely advertised.

GROUP IV

The utilisation of a foam blanket consisting of very stable bubbles containing carbon dioxide is comparatively modern, and is a most interesting application of the laws of surface adsorption, a branch of chemistry to which much attention has been directed during the last ten years. In essence, the process consists in bringing together a solution of sodium bicarbonate and a solution of aluminium sulphate, which leads to the evolution of carbon dioxide and the setting free of colloidal alumina. To this solution certain organic materials are added, such as liquorice or saponin, which act as foam formers and stabilisers. In the earlier form of instruments sodium bicarbonate and the aluminium sulphate were in two separate packets, and the remaining material was generally supplied in solution in a tin. At a later date the organic matter in a solid finely divided form mixed with the sodium bicarbonate formed one charge and the aluminium sulphate the other. Small hand machines were made much on the lines of the soda and acid machine, as well as plant of the 30-40 gallon type on wheels, but for the protection of oil storage tanks and for use on the steamships where oil firing is employed, large permanent tanks were used, with or without thermostatic control. The latest advance is by the utilisation of processes which can be adapted to an existing water supply and which will give a continuous discharge of foam so long as the necessary dry admixture of chemicals is supplied to the plant. In effect a mixture of finely divided and very dry sodium bicarbonate and aluminium sulphate with the organic foam stabiliser is fed into a water supply at a rate proportional to the rate of water flow and foam thus produced in the water circuit itself. The foam is now made having such physical characteristics that it will adhere to vertical surfaces and the duration or life of the foam is much greater than was obtainable a few years ago. The Board of Trade have made it necessary for all oil-using steamers carrying passengers to have installed apparatus capable of giving a fire extinguishing layer of a given thickness over the whole of the boiler room floor. In a few cases, possibly to save expense, steamships have employed cylinders of liquid carbon dioxide which may be caused to discharge their contents on to the engine room floor. It should, of course, be borne in mind that a mere reduction of the oxygen content of the air is sufficient to render most bodies non-combustible, and it is not necessary entirely to exclude oxygen, but the higher the temperature and the more the fire has advanced, the smaller the percentage of oxygen which will continue to support combustion. In America and in this country very large electrical generating sets are frequently protected by carbon dioxide installations, and it is interesting to note that the voltage necessary to pass a spark through carbon dioxide is greater than that necessary through air. In some of the American installations, the carbon dioxide cylinders are contained in a frame which forms one scale of a balance, so that it is possible at any moment to know what weight of liquid carbon dioxide is contained in the stand and to check loss by leakage. As electrical fires are liable to smoulder, there is an ingenious device for permitting a slow evolution of carbon dioxide for a

period of some hours after the apparatus has first been called into action, and this delayed discharge is quite automatic. Clearly for the protection of large electrical units chiefly carbon dioxide and carbon tetrachloride installations come into question.

A great deal of work has had to be done in order to devise nozzles from which the liquid carbon dioxide could be discharged without freezing up the nozzle. At present a special design of Monel metal nozzle is used which appears to get over the difficulty. In marine use a very real difficulty arises from the extraordinarily low temperature at which the carbon dioxide gas is set free on the engine-room floor when it is released from the liquid carbon dioxide contained in the storage vessels.

General

The growing use of nitro-cellulose for paints, varnishes, films, combs, knife handles etc. has introduced new risks into daily life. In so far as nitro-cellulose is employed we have a product containing in itself a large amount of oxygen and capable of combustion without the employment of external oxygen from the air. The box of film, if combed out and ignited, can be plunged into a tank full of carbon tetrachloride and it will still continue to burn and to give off inflammable gases, and it will burn equally well covered with a heap of dry sand. Such continued combustion in the absence of external oxygen is, however, only possible when the film or objects are really violently aflame. Small cellulose fires are amenable to extinction if caught at an early enough stage. A similar difficulty arises in handling fires in which nitrates or chromates are concerned, for here again the oxygen is contained within the material itself. Attempts to extinguish a mass of burning sodium by means of carbon tetrachloride were also doomed to failure, for the sodium combined with the chlorine and set the carbon free, and the fire, if anything, was a greater success after treatment than before.

A POSSIBLE NEW FACTOR IN THE CHEMICAL MECHANISM OF MUSCULAR CONTRACTION*

BY P. EGGLETON AND M. G. EGGLETON

Since the discovery by Harden and his colleagues of the importance of phosphates in the fermentation of glucose by yeast, the possibility has had to be considered that phosphates may play a similar rôle in the breakdown of carbohydrates which is known to accompany muscular contraction. In a study of the significance of phosphates in this connexion we have obtained some results which seem to suggest that the problem contains complications not previously suspected. It was found¹ that resting voluntary muscle contains a substance, apparently an ester of phosphoric acid, which, owing to the rapidity with which it gives rise to inorganic phosphate in acid solution, had been hitherto confused with inorganic phosphate; for the estimation of phosphate in muscle is usually carried out in strongly acid solution.^{2,3} When a satisfactory technique had been found for the separate estimation of this substance and true inorganic phosphate, it was shown

that the substance disappeared rapidly (though never completely) from an isolated muscle during a tetanus, with a simultaneous appearance of inorganic phosphate in addition to the appearance of lactic acid. Subsequent recovery of the muscle in an atmosphere of oxygen led to a rapid reconstitution of this substance (with a corresponding disappearance of inorganic phosphate). This reconstitution was much more rapid than the oxidative removal of lactic acid.⁴ These facts led us to apply the name "phosphagen" to this substance pending an examination of its chemical nature.

In view of the work of Meyerhof on the "fermentation" of carbohydrates by cell-free muscle extracts, and his demonstration of the part played by the intermediate formation and decomposition of hexosephosphates it seemed possible that we had discovered some labile hexosephosphate which might be the precursor of the lactic acid which is formed during exercise. The ratio of phosphagen disappearing, to lactic acid formed, was quite consistent with this view. Our attempts to isolate phosphagen therefore resolved themselves into the isolation of the hexosephosphates of muscle, and up to a point the results tended to confirm this idea. If the proteins are removed from a muscle by the use of trichloroacetic acid, and the filtrate is neutralised with barium hydroxide (to pH 8), a precipitate is obtained which consists chiefly of barium phosphate: it contains no phosphagen. The addition of an equal volume of alcohol brings down a further precipitate which contains all the phosphagen of the muscle, as would be expected if phosphagen were a hexosemonophosphate. An examination of this precipitate showed it to contain carbohydrate in combination with phosphoric acid. However, only half of the phosphorus present was usually in the form of phosphagen. By a process of systematic fractionation (according to solubilities in aqueous alcohol) the phosphagen phosphorus could be concentrated in the more soluble fraction of this material. It was at this stage that it became doubtful whether we were dealing with a hexose derivative at all, for the purer we obtained the phosphagen (as judged by the increasing proportion of labile phosphorus) the smaller grew the optical rotation and the copper-reducing power of the material. In this manner we obtained a preparation having the following constitution:—

Phosphagen phosphorus ...	6.3%
Total phosphorus ...	7.95%
Barium ...	36%
Copper reduction (Folin's method) ...	11% (as glucose)
Optical rotation ...	+3° (mercury green light).

At this stage further fractionation was abandoned owing to its inefficiency. An effort was made to isolate the organic moiety of the phosphagen molecule. A preparation of phosphagen containing 60% of its phosphorus in the labile form was dissolved in decinormal hydrochloric acid and allowed to stand overnight. Barium phosphate was slowly precipitated, and after 12 hrs. no phosphagen could be detected. After removing unchanged barium salts by precipitation with alcohol, and evaporating the filtrate *in vacuo*, a crop of crystals was obtained which accounted for about 15% of

* Communicated from the Department of Physiology and Biochemistry, University College, London

of the weight of the material taken. The crystals were well-formed rhombic prisms, melting at 256° C. Recrystallisation from hot water did not change the melting point. This substance dissolved in about 100 pts. of cold water, but was very soluble in hot water; it was insoluble in all the common organic solvents. Dried *in vacuo* over sulphuric acid it became amorphous, and lost about 11% of its weight.

At this point our attention was directed (by a private communication from Prof. A. V. Hill) to a paper read by Fiske in April, in which he described a substance resembling phosphagen in its properties, which he stated to contain creatine. An examination of the crystals we had isolated gave confirmation of Fiske's statement. The substance, after boiling with dilute acid, yielded a crystalline picrate identical in appearance and melting point with creatinine picrate (m.p. 212–213°), and its melting point was not lowered by admixture with the latter. The original crystals were found to contain 29% nitrogen.

Distribution of creatine and phosphagen in successive stages of isolation of phosphagen

Creatine (in millimoles) present in			Phosphagen (in millimoles of P) present in		
Insoluble fraction.	"Phosphagen" fraction	Soluble residue.	Insoluble fraction	"Phosphagen" fraction	Soluble residue
	10.40			2.94	
0.07	1.56	8.14	1.77	1.84	0.32
0.08	0.92	0.51	0.05	0.87	0.13
0.44	0.36	0.02	0.38	0.31	Trace
		(hydrolysis)			
Trace	Trace		Trace	Trace	Trace

* This fractionation was carried out with 25% alcohol instead of 15%, thereby bringing down some of the phosphagen in the "insoluble" fraction.

The possibility had to be considered, however, that free creatine might have been associated with the phosphagen fraction through similar solubilities. A fresh preparation was therefore made from muscle, in which the distribution of creatine and phosphagen phosphorus was followed at every stage. The results furnish a strong indication that one molecule of creatine is intimately associated with each atom of phosphagen phosphorus. It will be seen from the diagram that the protein-free muscle extract with which we started happened to contain about three molecules of creatine (estimated by Folin's method) to each atom of phosphagen phosphorus. In the first crude phosphagen precipitate this ratio had fallen to less than 1:2, the excess of creatine appearing in the aqueous-alcoholic filtrate. Two successive fractionations reduced this ratio to 1:07. At this stage we had 207 mg. of a substance containing 5.1% phosphagen P and 7.3% creatine N. When this material was hydrolysed as described earlier, the phosphagen phosphorus was nearly quantitatively recovered as barium phosphate (see diagram), and the creatine which had been associated with it now appeared quantitatively in the aqueous-alcoholic filtrate.

As early as 1914 Folin⁵ expressed the view that in living muscles creatine probably exists in a combined form, a combination broken down after death. Further, it has been shown by Beker⁶ and others that creatine is most abundant in voluntary muscle, less so in cardiac muscle, and present only in traces in plain muscle. We have shown in an earlier paper that the same is true for the distribution of phosphagen. We therefore think it reasonable to suppose that creatine is associated intimately with that complex which we have designated phosphagen, and that, therefore, creatine has a part to play in the chemical phenomena accompanying muscular contraction and recovery.

In conclusion, we wish to record our gratitude to Prof. J. C. Drummond for his generous advice and help in this work.

CANADIAN INDUSTRIAL NOTES

The Dominion Bridge Company is erecting a plant costing about \$300,000, at False Creek, Vancouver, B.C., for the fabrication of steel products. British Columbia is not a steel-producing province.

Canada's export of rubber goods in 1926 had a total value of \$25,620,462, an approximate increase of 10% over the exports of 1925, when they amounted to \$17,135,892. Pneumatic tyre casings, valued at \$14,645,309, formed the chief item. Great Britain was the principal direct purchaser of casings, taking about 18% of the total exports by volume. Argentina, New Zealand, Brazil and Australia followed in order, and these five markets took almost 50% of the casing exports by volume. The value of the inner tube exports was \$2,567,105. The chief markets were the same as the casings, except that Brazil and New Zealand exchanged positions. Solid tyre exports were unimportant, amounting in value to \$312,526. Great Britain and Japan were the most important purchasers with goods valued at \$44,512 and \$32,836 respectively.

The year 1926 was one of the best which the Steel Co. of Canada has experienced in its history. Manufacturing profits were \$3,247,606, as compared with \$2,825,606 in 1925. Income from investments brought the total to \$3,644,291. This was disbursed as follows:—Sinking fund \$292,269, depreciation \$760,208, bond interest \$362,601, and preferred dividends \$454,741. These charges left the sum of \$1,774,470 available for dividends on common stock, as compared with \$1,363,567 in 1925 and \$1,069,768 in 1924. The common dividend absorbed \$805,000, leaving a balance of \$969,470 from which was transferred \$100,000 to a new reserve for employees' welfare and benefit, and the balance credited to profit and loss account, which now stands at \$10,163,054. Total assets of the company are given as \$51,549,893.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

In accordance with the provisions of By-Law 68, notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Debating Hall, University Union, Edinburgh, on Tuesday, July 5, 1927, at 10 a.m.

A detailed programme with form of application for tickets for the various functions is being issued to members.

In accordance with the provisions of By-Law 23, notice is hereby given that the following Members of Council retire from their respective offices at the forthcoming Annual General Meeting:—

Mr. Francis H. Carr, C.B.E., *President*: Dr. E. Frankland Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., *Vice-Presidents*: Mr. W. A. S. Calder, Mr. W. H. Coleman, Dr. William Cullen, and Mr. J. Arthur Reavell, *Ordinary Members*.

Mr. Francis H. Carr, C.B.E., has been nominated for re-election to the office of President under By-Law 19. Mr. E. V. Evans, Mr. C. S. Garland, Dr. H. Levinstein, and the Right Hon. Sir Alfred Mond, Bart., M.P., have been nominated Vice-Presidents under By-Law 20. Dr. E. W. Smith has been elected Honorary Treasurer, and Dr. E. Frankland Armstrong, F.R.S., has been elected Honorary Foreign Secretary.

Mr. A. J. Chapman, Dr. H. E. Cox, Dr. W. M. Cumming, Mr. George Gray, Mr. C. Norman Kemp, Prof. G. T. Morgan, F.R.S., Dr. F. L. Pyman, F.R.S., Mr. L. Guy Radcliffe, Prof. Joseph Reilly, and Mr. Harold Talbot have been nominated under By-Law 24 to fill four vacancies among the Ordinary Members of Council.

A Ballot List is being posted to every Member entitled to vote.

J. P. LONGSTAFF,
General Secretary

CALENDAR OF FORTHCOMING EVENTS

- May 28. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, *Associates' and Students' Section*. The Mining Institute, Neville Hall, Newcastle-upon-Tyne, at 3 p.m. "Variable speed gears and their application for colliery purposes," by W. S. Armstrong. (Illustrated by lantern slides.)
- May 31. ROYAL PHOTOGRAPHIC SOCIETY, 35, Russell Square, W.C.1. "The development of chloro-bromide papers" and "The exposure of colour-screen plates," by E. A. Bierman.
- June 2. CHEMICAL SOCIETY, Burlington House, London, W.1, at 8 p.m. *Ordinary Scientific Meeting*.
(1) "The passivity of metals. Part I.—The isolation of the protective film," by U. R. Evans.
(2) "Studies of valency. Part VIII.—The molecular structure of Vernon's dimethyltellurium salts," by Prof. T. M. Lowry and R. R. Goldstein.
(3) "The factors controlling the formation of some derivatives of quinoline, and a new aspect on the problem of substitution in the quinoline series," by E. Roberts and E. E. Turner.

THE INSTITUTION OF CHEMICAL ENGINEERS

Recent Elections

Full Members

- Airey, F. T., B.Sc., Superintendent of the Chemical Section of the Salt Union, Ltd., Weston Point.
Whitelock, E. D., Chief Engineer, Brotherton & Co., Ltd., Leeds.
Powell, D. H. G., Chemical Engineer, Oil Mills, Punjab.

Transferred from Associate-Membership to Full Membership

- Barber, C., Chemical Engineer and Manager, Coke Oven By-Product Department, Norton's (Tivdale), Ltd., Tipton.
Bingham, J. H., A.M.I.Mech.E., Chevalier de l'ordre de la Couronne, Works Manager of Geo. Glover & Co., Ltd., Chelsea.
Webb, H. W., M.Sc., F.I.C., Head of Department of Chemistry and Industrial Chemistry, and Lecturer in Chemical Engineering, Cardiff Technical College.

Associate-Members

- Ambrose, A. J., Engineer to Manly Gas Company, near Sydney, N.S.W.
Dallas, W., A.I.C., A.I.M.M., Chemist and Assistant Manager to Brand's Pure Spelter Co., Ltd., Irvine, Ayrshire.
Green, A. T., F.Inst.P., Technical Adviser to Derbyshire Silica Firebrick Co., Ltd., Friden, near Buxton.
Johnson, W., Carbonising Superintendent on Vertical Retort Installations; c/o Wests Gas Improvement Co., Ltd., Miles Platting, Manchester.

Transferred from Graduate-ship to Associate-Membership

- Heggie, R. G., B.Sc.(Eng.) in Chemical Engineering; Chemist, South African Railway and Harbour Administration Laboratory, Workshops, Pretoria.

Graduates

- Colton, W. J., Assistant with Ruston & Hornsby, Ltd., Lincoln.
Emler, K. L., B.Sc., A.R.C.Sc.
Hickson, H. E., B.Sc. (Tech.).
Manchester
Rogers, R. C., B.Sc., A.R.C.Sc.
Franklin, H. B., B.Sc., A.R.C.Sc.,
D.I.C.
Swallow, J. C., B.Sc., Ph.D., on Research Staff of Brunner, Mond & Co., Ltd., Northwich.

Student

- Hayman, R. F., Assistant with Messrs. A. Boake Roberts & Co., Ltd., London.

CHEMICAL SOCIETY

The Faraday lecture was delivered on May 18, at the Royal Institution, by Prof. Dr. Richard Willstätter, the President, Prof. H. Brereton Baker, C.B.E., F.R.S., presiding over a large gathering of Fellows and distinguished guests, among whom was the Right Hon. the Earl of Balfour, K.G., F.R.S. The President, introducing the lecturer, said that the occasion was not a memorial lecture, but a triennial discourse whereby they rendered homage to the name of Faraday, a name which would be honoured as long as science was studied. Those who had been invited to deliver the Faraday lectures had been among the most celebrated scientists from all parts of the world. Faraday and the lecturer had both chosen the frontiers of chemistry as their

campaigning ground, and had largely extended our knowledge of its borderland.

Prof. Willstätter, taking as his subject "Problems and methods in enzyme research," first referred to Faraday's experiments "on the power of metals and other solids to induce combination of gaseous bodies," and proceeded from a consideration of inorganic catalysis to deal with the organic catalysts, developing the parallelism which had been recognised even in the earliest observations of the phenomenon. The modern progress of industrial catalysis had emphasised the problem of improving inorganic catalysts on the pattern of the enzymes, so as to make them more selective as well as more active. In investigations on the behaviour of hydrogen and oxygen with platinum the lecturer had found reason to believe that a new contact substance was produced: that platinum charged with oxygen must be considered as a mixed catalyst. Similarly, the behaviour of activated enzymes suggested that mixtures may be of the nature of new chemical compounds. The gulf between the inorganic catalysts and the enzymes, which are still of obscure chemical constitution, had now been bridged by accurately defined organic compounds which behave like the latter.

The conception of the enzymes as specific organic compounds led Prof. Willstätter to discuss the problem of isolating them in a state of purity. The processes are accompanied by determinations of the relative activity of the preparations, whereas in the production of inorganic catalysts it is customary to be satisfied with the conversion of an unknown small fraction of the atoms of the crystal structure into an active condition. The processes of separation were based on adsorption, which could be made so selective that enzymes could be largely freed not only from foreign admixtures, but also from their activators, the enzymes being subsequently removed from the adsorbates by gentle chemical treatment. In this way it could be shown that phosphorus and iron are not essential constituents of invertase and peroxidase respectively, but there is no certain method of freeing the enzymes from the protein derivatives. For separating enzymes from those substances which they most closely resemble in colloidal and chemical properties, a process of adsorption on a very finely divided precipitate, e.g., of lead phosphate, produced in the enzyme solution itself, is employed. It had thus become possible to separate an enzyme even from the products of its inactivation (by keeping or warming), which differ only in the absence of the active specific group. By adsorption, also, complete resolution of the proteolytic system of the pancreas and the intestine had been attained: in many cases the atomic groups responsible for the union of the enzyme to the adsorbent were indicated, and delicate gradations of adsorptive power are determined by the peculiar chemical differentiation of the gels used. So far as is known, the only property of enzymes which is independent of their varying degree of purity is their qualitative specificity, and in this connexion it is even possible to ascertain the particular atomic group of the substrate molecule towards which their enzymic activity is directed.

At the conclusion of the lecture the President, in presenting the Faraday medal to Prof. Willstätter, expressed the hope that it would be a happy souvenir of this great occasion. A vote of thanks to the lecturer was proposed by Prof. W. H. Perkin, F.R.S., who referred appreciatively to Prof. Willstätter's splendid work in pure organic chemistry as well as in biochemistry. Prof. J. F. Thorpe, C.B.E., F.R.S., seconding, said that the lecturer's researches entitled him to be placed on a pinnacle with his great countrymen Baeyer and Fischer. The motion for the vote of thanks having been put by the President and carried with enthusiasm, Prof. Willstätter, in acknowledgment, expressed his sincere thanks for the opportunity both of sharing in the tribute to Faraday and of reciprocating a desire to unite the scientists of every country. A vote of thanks to the Managers of the Royal Institution for permitting the use of Faraday's lecture theatre was carried with acclamation.

At an ordinary scientific meeting, held on May 19, Professor Dr. Richard Willstätter was admitted an Honorary Fellow. The President, Professor H. Brereton Baker, C.B.E., F.R.S., reminded Fellows that applications for grants from the Research Fund must be received by June 1.

Prof. H. M. Dawson then gave a general account of his investigations on acid catalysis and the catalytic catenary in the following paper:—

New Developments in the Study of Acid Catalysis The Catalytic Catenary

THE long continued acceptance of the view which ascribes the catalytic activity of acids entirely to the hydrogen ion is largely due to the circumstance that this theory is in approximate agreement with a considerable body of facts. Outstanding anomalies, such as are presented by the salt effects observed in the catalytic action of strong acids, have been accommodated by the introduction of ad hoc hypotheses.

More detailed and accurate investigations of acid catalysis led subsequently to the idea that the undissociated acid also plays the part of a catalyst. Notwithstanding the very strong evidence of the dual theory of catalytic activity, it has received comparatively little attention. On the other hand, the suggestion that the facts may be explained in terms of variations in the activity of the hydrogen ion seems to have had undue weight attached to it. It is possible that such variations cannot be ignored, but there can be little doubt that the deviations from the simple hydrogen ion theory are mainly due to the circumstance that the observed catalytic effects are not entirely due to the hydrogen ion, but represent the joint action of hydrogen ions, acid anions, and undissociated acid molecules.

If a comparison is made of the catalytic activities of mixtures of a weak acid and its corresponding salts, represented by the formula $cHA + xMA$ (where c is constant and x is variable), it will be found very generally that as x increases the reaction velocity falls, reaches a minimum, and then increases. If the velocity is plotted against p_H , a curve of catenary type is obtained.

The experimental facts are expressed by the equation $v = k_h[H^+] + k_a[A^-] + k_{OH}[OH^-] + k_m[HA] + k_w[H_2O]$ and this, in combination with

$$K = \frac{[H^+][A^-]}{[HA]} \text{ and } K_w = [H^+][OH^-]$$

may be shown to give a catenary curve when v is plotted against pH .

The dimensions of the catenary curve and the position of its minimum (iso-catalytic) point vary with the concentration of the acid. The complete series of catenaries yields a catalytic space model in the form of a catenary surface, by means of which it is possible to represent the catalytic behaviour of all possible mixtures of an acid and its salts.

The catalytic catenary may be given a generalised form, for if the hydrogen ion concentration and the ionic reaction velocity for any acid-salt mixture are expressed in terms of the corresponding quantities which are characteristic of the iso-catalytic mixture with the same acid concentration, the connexion between the reduced ionic velocity (r) and the logarithm of the reduced hydrogen ion concentration (h) is given by

$$r = \cosh h.$$

This equation contains no specific constants, and is therefore independent of the nature and concentration of the catalysing acid, of the temperature of the solvent, and of the nature of the catalysed reaction. It is the equation of the general catenary, and is found to be consistent with known facts.

For a given reaction the catalytic activities of the pure acids are represented by points on the general catenary, the position of these points being determined by the relative magnitudes of the velocity coefficients of the hydrogen ion and the undissociated acid anion.

The considerations underlying the general theory have been applied successfully to the phenomena associated with reaction velocity in isohydric solutions and in buffer solutions, and also to the phenomena of auto-catalysis. Kinetic methods have been described for the determination of ionisation constants, of velocity coefficients which cannot be obtained by direct measurement, and of the degree of dissociation of water. The general results are such as to offer a very comprehensive picture of the catalytic relations involved in acid catalysed reactions, and throw new light on the nature of acids and their relation to the so-called bases.

Dr. E. K. Rideal said that the author had interpreted the velocity curve in terms of four different velocity constants, permitting a certain latitude in adjustment, yet he had so devised his experiments as to justify this course. He asked how far Prof. Dawson had considered the mechanism of the reaction, *e.g.*, in terms of Wieland's conception of hydrogen ion donation and acceptance, H^+ and HA providing hydrogen ions and OH^- and A^- accepting them. This two-stage process would lead to the catenary if the product $[H^+][OH^-]$ was constant. He also asked how far neutral salts such as sodium chloride affected the velocity, *i.e.*, how far hydration is an important factor in these changes.

Prof. H. Bassett remarked that curves correlating the time necessary for the first appearance of sulphur in acidified thiosulphate solutions with the acid concentra-

tion are closely of catenary form. The time-minima were attributed to the opposition of two opposing reactions, the formation of sulphurous acid and sulphur (producing free sulphur) and the formation of polythionates (consuming free sulphur).

Prof. J. C. Philip asked whether the author had considered the relation of his results to modern views on ionic environment.

Prof. H. M. Dawson, replying, said that no attempt had yet been made to apply the results in the direction of elucidating the mechanism of the catalytic process so far as the catalysed reaction itself was concerned. The main object had been to identify the active entities and to correlate their effects. Whilst the effects produced by the addition of chlorides to hydrochloric acid would seem to differ from those produced by the addition of salts to the corresponding weak acids, there was reason to believe that no fundamental difference is involved. The phenomena discussed by the author referred to a specific reaction, and the speaker emphasised that the catenary relation between v and pH is *exact* within the limits of experimental error. The $v - pH$ curve would be catenary in type if the conditions were such that the product of the concentrations of the active ions remains constant. Attempts to interpret the observations in terms of changes in the "activity" of the hydrogen ion had not met with success. The selective nature of the catalytic effect suggested that ionic environment is not a factor of primary importance.

MINING AND METALLURGY IN CANADA

The Rouyn area in Quebec, north of Ottawa, which has been attracting attention, is fast developing into a large mining district. It is anticipated that the Noranda Mines, Ltd. (Horne Mining Company operating subsidiary), will be operating its large smelter in November next. The railway into Rouyn has been completed, and machinery and materials are being transported in large quantity. The report, just issued, shows the ore reserves of the Horne Mine have a gross value of \$25,100,000, on the basis of copper at 13 cents per lb. At the close of 1926 the indicated tonnage is shown at 1,022,425 tons of ore, having a grade of 5.03 gold and 7.51% copper, all above the 300 foot level. These estimates are considered to be conservative. In shaft No. 2 sufficient work has been done to show 53,000 tons, averaging 10.4% zinc, but more diamond drilling remains to be done before the limits of this ore body are determined. Electrical power having been introduced, further development will be pushed forward. The construction of the smelter, buildings and houses is proceeding rapidly. The Hollinger Company is a large holder of the Noranda bonds. The general manager of the Horne Mining Company is Mr. Ernest Hibbert.

The earnings of the Premier Gold Mining Company of British Columbia for 1926 amounted to \$2,211,490, a gain of \$198,000 over the return of last year. The estimate of broken and unbroken ore reserves, down to the fifth level of the present mine workings, is 798,269 tons averaging 0.48 oz. gold and 9.6 oz. silver, having a gross value of \$14.40 a ton, with silver at 50 cents per oz.

OBITUARY

WILLIAM BEAMONT HART, F.I.C.

With the death, on December 29, 1926, of William Beamont Hart, the chemical world of Manchester lost a highly respected member. Born on March 1, 1865, Mr. Hart was educated at Manchester Commercial Schools and at Owens College, where he became Roscoe Scholar in 1885. He gained several successes in the City and Guilds examinations, and was awarded the Silver Medal twice, in 1885 for the examination on alkali manufacture, and in 1886 for that on coal-tar products, for which subject he was awarded the Bronze Medal in 1888. After leaving Owens College he was engaged for some time with the Clayton Aniline Company, but in 1892 established himself in practice as an analytical and consulting chemist. From 1895 to 1900 he visited Constantinople on behalf of the Turkish Government in connexion with the manufacture of sulphuric acid and smokeless powder. For these services he was presented with the Order of the Osmanieh in 1902.

Mr Hart was held in high repute in Manchester as a chemist, and was retained by several firms in an advisory capacity. He took a great interest in the work of the Institute of Chemistry and of the Society of Chemical Industry. He served on the local Committees for several years, and contributed papers to the meetings of the Manchester Section of the Society.

GEORGE SISSON

By the death of George Sisson through a motor accident at the beginning of April the technical chemical world, and especially that of Tyneside, has suffered a severe loss.

Born in Gateshead in 1856, he received his scientific education at the University of Durham College of Physical Science (now Armstrong College) in Newcastle-upon-Tyne, and as a Royal Exhibitioner at the Royal College of Science, Dublin. He went as chemist to the works of the Washington Chemical Co., in the county of Durham, taking part later in the management; here he remained (with an interval of about three years from 1890, when he worked with Messrs. Peter Spence & Sons, Manchester) till 1905. In the early years of this period the Chance-Claus process for the recovery of sulphur from alkali waste was introduced into the works, and later a process for the manufacture of magnesia from sea water was developed, and one for the recovery and liquefaction of the carbon dioxide gas, which was till then a waste product of the magnesia process.

On leaving the Washington Chemical Co., he practised for a few years as consulting technical chemist, and then accepted a position as technical adviser to, and later as managing director of, the Blaydon Manure and Alkali Works, which he occupied till his death, and in which position he entirely reorganised the works.

He was always fond of natural history, and did much work in research with Professor Meek at the Marine Biological Laboratory of Armstrong College at Cullercoats. He was for many years a member of the Society of Chemical Industry, and read before the Newcastle Section, with his brother, Mr. Harry Sisson, an important paper on liquefied carbon dioxide.

He was an accomplished chemist, independent in his thought, and sound in his judgments; and he had an almost instinctive sense of the industrial possibilities (or lack of possibilities) of a laboratory reaction. In his technical advice he was always "safe," yet he had an open and unprejudiced attitude of mind towards new ideas and suggested processes. He was a man of strong common sense and always helpful.

His personal qualities endeared him to all with whom he came into contact. His demeanour, natural and unassuming, his equable disposition, a certain serenity, that was suggested in his leisurely speech, his sense of humour and enjoyment of paradox, and his unfailing kindness, made him the most approachable of men, and drew esteem and regard from even slight acquaintances; and those who were privileged to enjoy his intimate friendship, and had revealed to them his simple, just, and upright character, of which those qualities were the natural outcome, can only mourn the loss of his sunny personality, "Whose coming was as light and music are, 'mid dissonance and gloom," and cherish the memory of it among their most precious possessions.

J. T. DUNN

PERSONAL AND OTHER ITEMS

On the occasion of the visit of Monsieur Doumergue, the President of the French Republic, to the Institut Français du Royaume Uni, he presented the decoration of Officier de la Légion d'Honneur to Mr. Emile Mond, who is a member of council of the Institut.

Emeritus Professor A. G. Perkin will receive the honorary degree of D.Sc. from the University of Leeds in July.

Mr. C. A. Klein has been elected President and Prof. T. M. Lowry, Dr. H. H. Morgan, and Messrs. W. S. Morris and T. M. Tyson have been elected Vice-Presidents of the Oil and Colour Chemists' Association for the session 1927-28.

Mr. Sidney S. Napper, who has been a director of British Visada, Ltd., since the beginning of the year, and consultant chemist to the firm, has been appointed managing director. Mr. Napper was works and chief research chemist to Courtaulds, Ltd., for 18 years.

Mr. Christopher Dalley and Mr. Richard R. Tweed, the technical directors of the British Controlled Oilfields Company, have been appointed joint general managers for a term of years. Mr. G. W. Halse has joined the geological staff.

Prof. C. A. Edwards, professor of metallurgy and acting principal of the University College of Swansea, has been appointed Principal of the College in succession to Dr. Sibly. Prof. Edwards will continue to act as professor of metallurgy, and will supervise the work of honours students and direct research in the department.

Dr. W. E. Garner has resigned from the University Readership in Physical Chemistry tenable at University College, London.

Amongst the 20 Fellowships tenable in American Universities awarded by the Commonwealth Fund Fellowships, Mr. R. Robinson, of Birmingham University,

has been appointed to a Fellowship in physical chemistry at the University of Pennsylvania.

A national research fellowship (U.S.A.) has been awarded to Dr. J. Allen Harris, Assistant Professor of Chemistry, University of British Columbia, and co-discoverer of illium with Dr. E. S. Hopkins. He will take up post-graduate studies at the Sorbonne, Paris, and University of Upsala.

The Plummer gold medal for 1926 has been awarded by the Engineering Institute of Canada to Deau C. J. Mackenzie (engineering) and Prof. T. Thorvaldson (chemistry), of Saskatchewan University, for researches upon the prevention of the deterioration of concrete arising from the presence of alkaline-earth salts in certain soils of the Canadian Western provinces.

We regret to announce the death, at the age of 72, of Mr. Frank Lloyd, head of the important paper-making firm of Edward Lloyd, Ltd.

Imperial Chemical Industries, Ltd., and Cassel Cyanide Co., Ltd.

It is announced that an offer has been made by Imperial Chemical Industries, Ltd., to acquire the shares of Cassel Cyanide Co., Ltd., and that the directors of the latter company recommend acceptance by their shareholders. Particulars are given in Company News on page 496.

Low-Temperature Carbonisation

It is understood that International Combustion, Ltd., and Imperial Chemical Industries, Ltd., have come to a working arrangement, mainly designed for the development of low-temperature carbonisation in Great Britain. Two large plants are to be erected, one utilising the McEwen Runge process and the other the Kohlen-scheidung process, which has been worked for some years in Germany.

Research on the Treatment of Coal

Speaking recently at the House of Commons, Dr. G. C. Clayton, M.P., a director of Imperial Chemical Industries, Ltd., and a member of the Advisory Council of the Department of Scientific and Industrial Research and of the Fuel Research Board, said that the Bergius plant at the Fuel Research Station was dealing with a ton of coal a day, and was giving very good results. There was a danger some time ago that the British Empire rights of the Bergius process might be lost to this country, but the Department advised the Government to get some control over this patent, and an option on a considerable amount of the interest in the British rights of the Bergius process had now been acquired by Imperial Chemical Industries, Ltd. The Bergius process had been developed up to a large experimental scale only, but a modification of the Bergius process had been worked out by the Interessens Gemeinschaft, who had got at work now a full large-scale plant, with an output of, roughly, 100,000 tons per annum of coal oil. The plant was now working, and he understood from members of Imperial Chemical Industries, Ltd., who paid a visit there a short time ago, that it was working extraordinarily well, and was going to be a commercial success.

Dealing with the present position of low-temperature carbonisation at the station, Dr. Clayton said that a

short time ago Sir David Milne-Watson, Governor of the Gas Light and Coke Company, was asked to investigate the low-temperature carbonisation processes that were in existence. Sir David was asked to see whether there was any process his company could take up as a commercial proposition, with or without Government assistance. After full investigation, he decided that the most suitable plant for adoption by his company to work, in conjunction with the ordinary gas process, was the plant designed by the members of the Fuel Research Board staff. That showed that the Fuel Research Board staff were deserving of very great praise for the work they had done. The Gas Light & Coke Company stated that, while they thought that that was the best process, they did not consider that they were justified as a company in bearing the entire cost of long experiment on this process, but offered a site for a plant to deal with 100 tons daily, to erect the plant, run it for three years and carry out investigations, if the Government would pay the cost of providing and erecting the plant. It has now been agreed by the Government and Sir D. Milne-Watson that the Gas Light & Coke Company shall form a subsidiary, the Fuel Production Co., Ltd., with capital guaranteed under the Trade Facilities Act, to carry out the proposal. The Gas Light & Coke Company will manage the new company and bear all costs, and will have the option of taking over the plant at the end of 1930. The scheme will, it is expected, be in operation next winter.

The Patent Office in 1926

The 44th report of the Comptroller-General of Patents, Designs, and Trade Marks for the year 1926 (H.M. Stationery Office, 4d.) states that the total number of applications for the year was 33,080, an increase of 77 on the number received in 1925. The complete specifications filed numbered 19,948, or 514 more than in 1925. Excluding the year 1920, when there was a post-war rush of applications, the number of complete specifications filed last year was the highest on record. The applications received from women inventors numbered 537, as compared with 608 in 1925. The applications made from abroad numbered 1390, as compared with 1547 in 1925. The receipts from patents fees were £398,391, from designs fees £10,834, and from trade marks fees £51,117, as compared with £391,677, £11,213, and £46,960 respectively for 1925. The total receipts were £488,152, as compared with £476,044 in 1925, an increase of £12,108. On the expenditure side, salaries amounted to £254,691, as against £254,952 in 1925. The surplus of receipts over expenditure was £98,813.

The Bulletin of the Imperial Institute

It has been decided to discontinue the publication of the Mineral Resources Section of the Bulletin of the Imperial Institute in the form in which it appeared during 1926. This course was adopted in consideration of the time required in preparing it and the pressing need for continuing the separate publication of monographs on specific subjects. In future, articles on minerals will appear only when there is some subject of outstanding importance to be dealt with. The publication of monthly statistics relating to minerals and metals will be discontinued, but can still be obtained by enquirers.

Applications for information on the mineral and metal industries will be attended to as heretofore.

An International Competition

The Fondazione per l'Incremento Culturale ed Economico della Sicilia announces that the following prizes are open for international competition: (1) The Stanislao Cannizzaro prize of 20,000 lire for an unpublished thesis on "The production of cellulose from Sicilian raw materials." (2) The Emanuele Paternò prize of 20,000 lire for an unpublished thesis on "The complete utilisation of the lemon." (3) Three prizes of 5000 l., 3000 l., and 2000 l., respectively, for theses on a subject related closely to the progress of chemical industries in Sicily. The competing theses must be sent in duplicate by registered post before the last day of February, 1929, to the "Fondazione per l'Incremento Culturale ed Economico della Sicilia," presso la Direzione Generale del Banco di Sicilia, Palermo. Further information can be obtained on applying to this address or to the

Associazione Italiana di Chimica Generale ed Applicata," Rome (101), via IV Novembre, 154, Italy.

Helium in Canada

Helium possesses many remarkable properties which may make it a very valuable industrial gas. It is an ideal gas for filling balloons and airships, for although it has 10% less buoyancy than hydrogen, it has the great advantage of being non-inflammable. An application of helium that promises to become of great value is its use in making up artificial atmospheres to supply to divers and caisson workers. An investigation, still in progress, by the U.S. Bureau of Mines has shown that there are great possibilities along these lines, and that such artificial oxygen-helium "airs" may permit of greater depths being attained and longer periods being spent under water by divers, and the prevention of caisson disease among tunnel and caisson workers. Suggestions for other industrial uses have been put forward, but outside of the United States no commercial supplies have yet been available, and there have been no opportunities for investigation and experiment.

From 1922 to 1926 the Mines Branch of the Dominion Department of Mines, as part of a survey of the natural gas resources of Canada, made a special study of the helium content of the gases, and a thorough examination was made of all possible sources of this element. It was found that the gas from three small wells at Inglewood, Ontario, contained as high a percentage of helium as that treated in the United States Government plant at Fort Worth, Texas. The Ontario Government has since taken up many of the leases in this neighbourhood, and it is anticipated that the National Research Council may establish an experimental helium extraction plant, if it be proved that sufficient gas is available. A few wells in other fields in Ontario, particularly in Norfolk county, yield gas carrying 0.5% helium. Natural gas in Alberta, where much larger quantities are available than in Ontario, was found to contain little or no helium, with the exception of that from the Bow Island and Foremost fields. If natural gas, containing as little as 0.2% helium, could be economically processed to extract helium, it is calculated that about 5 million

cub. ft. could be obtained in Canada annually (up to the end of 1926 over 25 million cub. ft. had been extracted by the U.S. Government). Canada is the only present known source of helium in the British Empire. The results of this investigation are described in a report, "Helium in Canada," by Dr. R. T. Elworthy, recently issued by the Mines Branch. It contains a brief account of the particulars and occurrences of helium, the methods employed in the work, particulars of the gas fields, including analyses of many gases, the methods and apparatus for recovering helium, and notes on its uses. Copies may be obtained on application to the Director, Mines Branch, Department of Mines, Ottawa, Canada.

Production of Asbestos in Quebec

Quebec is still the world's greatest producer of asbestos. Of the world's production of 340,000 tons in 1926, about 266,000 tons were produced in Quebec.

International Foundry Exhibition

An International Foundry Exhibition, organised by the Syndicat Général des Fondateurs de France, will be held in Paris in September. There will be three main groups of exhibits: raw materials, manufactured products, foundry materials and tools; and there will be sections for technical education and organisation within the foundry trade.

Output of Coal-Tar Dyes in the U.S.A.

The U.S. Tariff Commission Census shows further progress in the United States in the production of coal-tar dyes and chemicals, although the output of dyes in 1926 was still 5,000,000 lb. below the record reached in 1923. Sales of home-produced dyes in 1926 totalled 98% of the production volume. Exports remained the same as for 1925, and imports amounted to 5% of domestic production. In spite of increased production values fell, and there was a decline of 3% in total values of sales, the unit fall being from 46.6 cents a pound in 1925 to 42 cents in 1926. There was a still larger drop in the export trade, owing to competition with European manufacturers. In the last five years the total fall has been something like 50%, and in China and other countries of the East, American manufacturers make little or no profit. Of the total domestic output of finished coal-tar products, synthetic dyes constituted about 72%, and colour lakes, synthetic tanning materials, and phenol-formaldehyde resins made up about 20% of the total of 123,000,000 lb. In 1926 sales were 120,000,000 lb., worth about \$60,000,000. Outputs included 44,000 t. of synthetic dyes; 6000 t. of colour-lakes; 7000 t. of synthetic tanstuffs and resins; 900 t. of acetylsalicylic acid (aspirin); and 1200 t. of methyl salicylate (oil of wintergreen). The output of synthetic chemicals not of coal-tar origin was 105,000,000 lb., including 21,830 t. of ethyl acetate 15,975 t. of formaldehyde, 9500 t. of carbon tetrachloride, and 4600 t. of butyl acetate.

Synthetic Methanol in the United States

Lazote, Inc., a subsidiary of the du Pont Co., is now manufacturing synthetic methanol on a commercial scale at Belle, W. Va., in conjunction with the firm's synthetic ammonia plant.

REVIEWS

ESSAYS ON THE ART AND PRINCIPLES OF CHEMISTRY, INCLUDING THE FIRST MESSEL MEMORIAL LECTURE. By Prof. H. E. ARMSTRONG, F.R.S. Pp. xxxi + 276. London: Ernest Benn, Ltd. 1927. Price 15s.

Professor Armstrong's collection of "Essays on the Art and Principles of Chemistry" is in the main a reprint in book form of an article contributed to the 13th edition of the "Encyclopædia Britannica," and published in September, 1926. This, with an introduction describing the main features of the articles contributed to the ninth edition in 1876, to the tenth edition in 1902, and to the twelfth edition in 1922, occupies almost exactly one-half of the present volume. The other half contains two essays entitled "A Dream of Fair Hydron" and "The Thirst of Salted Water," published in 1909, an essay on "The Corrosion of Iron and other Metals" (1911), the first "Messel Memorial Lecture—Rhapsodies culled from the Thionic Epos" (1922), and two short papers on "The Origin of Osmotic Effects" and on "Electrolytic Conduction," reprinted from the Proceedings of the Royal Society (1923).

Since these reprinted essays are already familiar to readers of this JOURNAL, to which the Messel Memorial Lecture was first contributed, attention may be directed principally to the article in which the author, after a lapse of 50 years, again gives a review of the "Art and Principles of Chemistry," as it should be presented to the "man in the street," when he decides that it is time to spend an evening in discovering what chemistry is all about, and for this purpose takes down from its shelf the appropriate volume of the Encyclopædia. The task of condensing, for such a purpose, the theory and practice of chemistry into the narrow span of 120 pages is so formidable that we must all be curious to know how it has been tackled by the *doyen* of our science. The early steps are taken most ingeniously—fire, limestone, lime, "calcite gas" and oxygen, lead in a simple and direct way to quantitative data, based upon the standard $\text{CaCO}_3 = 100$, which needs no revision in order to convert it into the more familiar 0—16 scale, since the elements in question all obey the "whole number" rule within very narrow limits. The densities of the relevant gases are then used to lead up to Avogadro's hypothesis, and to the familiar atomic and molecular symbols, so that the classification of the elements on the basis of their atomic numbers and atomic weights is already reached within the first 25 pages. The next 35 pages are occupied with the physico-chemical problems of electrolysis, chemical change, catalysis, osmotic pressure and acidity, leaving almost exactly one-half of the available space for the problems of organic chemistry. The author has, however, been able in these remaining pages to discuss such diverse problems as the correlation of function and structure, stereochemistry old and new, oxidation and reduction, unsaturation, phenoid carbon, and colour, and then passes on to deal with plant activities, such as the fixation of carbon with the help of chlorophyll, the formation of carbohydrates, enzyme action, optical activity and

geometric structure of the sugars, constructive metabolism, proteins, the colloid nature of natural products and the problems presented by their dissolution. Whilst, therefore, the earlier part of the essay is remarkable for the ingenuity of its logical sequence, the latter part has the pleasing generality which made Schorlemmer's "Rise and Development of Organic Chemistry" such a delightful and valuable book to read.

In such a general review of the science of chemistry there is ample opportunity, but very little space, for controversy. Of special interest are the paragraphs which deal with Arrhenius' theory of electrolytic dissociation. The author's final conclusion, that hydrogen chloride is divisible under the influence of hydron, and is "distributed" according to some such scheme as

resembles so closely the current view, which represents the product as an ionised oxonium salt

that controversy can only arise as to the degree of freedom of the negative chloride radical in the product: but the further supposition, that the converse product $\text{HCl} \begin{array}{c} \text{H} \\ \diagup \\ \text{OH} \end{array}$ must also be present before electrolysis can occur, has no parallel in current theory.

The views summarised in the principal essay are set out in fuller detail in the essays which occupy the remainder of the volume. The last short essay, however, touches new ground in a discussion of Tubandt's observations on the electrolysis of solid crystalline silver iodide and lead chloride. In the former case there is a quantitative transference of *silver* between a silver anode and a platinum kathode, but no migration of the halogen; in the latter case, when a cylinder of silver iodide was interposed between the lead chloride and the silver anode, there was a quantitative transference of *chlorine* to the anode, but no migration of the metal. The validity of the explanations given of this opposite behaviour of the two solid salts may be open to dispute, but it is very fitting that so stimulating a book should conclude with an appeal to such arresting and unfamiliar facts.

STANISLAO CANNIZZARO: SCRITTI VARI E LETTERE INEDITE NEL CENTENARIO DELLA NASCITA. Pp. vii + 486. Published by the Associazione Italiana di Chimica Generale ed Applicata, Rome, 1926. Price 150 lire.

Last year the "Associazione Italiana di Chimica Generale ed Applicata" celebrated the centenary of the birth of Cannizzaro at Palermo. In addition to the ceremonies in which Italian chemists paid homage to their great compatriot, it was decided to publish a volume, not one containing the scientific papers of Cannizzaro—which are available in the "Nuovo Cimento" and the "Gazzetta"—but one in which his varied

activities as citizen, politician, scientist and teacher could be set forth by authoritative writers.

This has been done and the "Associazione" has published a handsome illustrated volume, which presents a detailed and fascinating picture of this many-sided man of science. Professor Paternò describes his qualities as a man; Prof. Giacosa discusses his contribution to physiological chemistry; his work in organic chemistry is dealt with by Prof. Bargellini; Prof. Parravano summarises the evolution of the atomic theory in relation to Cannizzaro's work, which is also discussed in a letter from Marcelin Berthelot, with comments by Prof. Nasini, who writes, in addition, on Cannizzaro and the theory of valency; Prof. Villavecchia shows his influence on the development of the Customs Laboratories; and Prof. Provenzani writes on the Italian school of chemistry. Then follows a series of unpublished letters from Baeuer, Beilstein, Berthelot, Frankland, Friedel, Kopp, Landolt, Leblanc, Liebig, Ludwig Mond, Ostwald, Ramsay, Kelvin, T. E. Thorpe, Wurtz, and various other well-known men of science. These varied contributions not only give a most attractive picture of the man, but enable the reader to recreate the atmosphere of the times in which he moved. The volume is a worthy tribute to the memory of Cannizzaro, and would grace the shelves of any chemist who cares for the history of his science.

PRACTICAL PHOTOMICROGRAPHY. By J. E. BARNARD, F.R.S., and F. V. WELCH. Second edition. Pp. xii + 316. London: E. Arnold & Co., 1925. Price 18s.

"Barnard" has long proved a strong arm to help the beginner in photomicrography and this new edition will be sure of a welcome. The authors observe that radical revision has not been necessary, as, though 14 years have elapsed since the book was first published, "microscopy has no outstanding advance to its credit, either on the optical or mechanical side." Attention is, therefore, mainly concentrated on method. Apparatus, of course, is fully described, and enough detail about optical equipment, sources of illumination, cameras, plates, etc. is given to guide the veriest beginner to success. Indeed, the whole book is remarkable for its attention to those practical details which make for successful photomicrography, and, if any criticism were to be made, it might be that there is too much detail. Thus, in such a book one does not require a description of the manufacture of calcium carbide; the wiring-up of arc lamps is best left to persons accustomed to the work; whilst the utility of including instructions for photographic development and after treatments may be doubted. No mention could be found of desensitisation, though the use of panchromatic plates is discussed. These are but minor points, however, for the book is not only a thoroughly safe guide for the beginner, but can be read with profit by the experienced worker. Photomicrography by ultra-violet light is treated shortly in a chapter on special processes (including the photomicrography of metallic and other opaque objects), as the authors intend to publish a book on that subject. The book is well produced and provided with excellent illustrations.

PARLIAMENTARY NEWS

Iraq (Oil)

In reply to various questions, Mr. Amery said that the only part of Iraq in which oil was at present being worked was in the area near the Persian frontier known as the Transferred Territories. The production was not at present large, though there were no actual figures. The Turkish Petroleum Company was the only concern searching for oil in Mesopotamia as far as he was aware. He could not say off-hand what amount of the capital of this company was British, but a certain proportion was held by the Anglo-Persian Oil Company, which was a British firm, and another portion, he thought 20%, was held by the Shell Company, which was 40% British. May 16.

Fuel Research

In reply to Mr. Tinker, the Duchess of Atholl said that the amount of coal treated at the Fuel Research Station, East Greenwich, during 1925 was 3314 tons. A considerable portion of the products from the coal carbonised was used at the Fuel Research Station. The value of the untreated gas and tar surplus to the requirements of the station and sold to the South Metropolitan Gas Company amounted to: gas £1249, and tar £318. In addition, £250 was received from sale of coke, the balance of gas and coke being used for other experimental work and for power production. The coal-washing plant, as with other large-scale plant at the station, was intended for investigations of general interest, and the coal required was usually purchased. Special investigations might be carried out for interested parties when the plant was available. In such cases the coal would be provided free, and a fee might be charged in addition, depending on whether the results were of general interest, and available for publication, or of restricted interest only.

The crude oil and spirit obtained from one ton of a suitable coal treated by the Bergius method amounted to from 110 to 135 gals. In addition, a further unknown amount of coal was necessary for power and hydrogen production. The highest yields of dry tar and spirit observed by the Fuel Research Board, as obtained from low-temperature carbonisation of ordinary coal in a large-scale plant, was about 21 gals., but average bituminous coal would probably not yield more than about 15 gals. Good quality cannel coal, of which there was a limited supply only, might yield 50 to 60 gals.—May 17.

Carbonisation (Statistics)

Colonel Lane-Fox informed Mr. Lunn that in 1925 approximately 30,200,000 tons of coal were used for high-temperature carbonisation and 20,000 tons for low-temperature carbonisation. May 17.

Zinc Concentrates Contract

In a written answer to Sir J. Power, Sir P. Cunliffe-Lister stated that the financial results of the zinc concentrates contract for the year ended March 31, 1927, could not, at present, be stated. A loss was anticipated of between £500,000 and £600,000 in the accounts for both the past and the current financial year.—May 17.

Ethyl Alcohol (Excise Duty)

Mr. McNeill informed Lieut.-Colonel Heneage that an investigation into the subject of substitutes for ethyl

alcohol had been made by the departments concerned, and as a result the following conclusions had been reached:—(1) Purified methyl alcohol will remain within the scope of the spirit duty. But no duty will be payable so far as it is used for industrial purposes, and the official supervision of manufacture and duty-free use will be reduced to the minimum consistent with the safety of the Revenue. Moreover, provision has been made in Clause 14 (1) of the Finance Bill for the extension to methyl alcohol of an appropriate Excise allowance on the lines of that now payable on ethyl alcohol manufactured in this country and used duty-free for industrial purposes, in order to compensate for the expense involved in conforming to Excise restrictions on manufacture; (2) as at present advised, it is not proposed to bring any other substance which may be used as a substitute for ethyl alcohol within the scope of the spirit duty. It is, however, proposed in Clause 15 of the Finance Bill to take power to collect information as to the importation, manufacture, distribution and use of the higher alcohols, and to require manufacturers of these substances to register with the Customs and Excise Department. May 19.

COMPANY NEWS

IMPERIAL CHEMICAL INDUSTRIES, LTD., AND CASSEL CYANIDE CO., LTD.

An offer has been made by Imperial Chemical Industries, Ltd., to acquire the shares of the Cassel Cyanide Co., the offer being conditional upon its acceptance by the holders of not less than 75% of the shares. The directors of Cassel Cyanide recommend shareholders to accept. Cassel Cyanide Co. is an old-established and prosperous Glasgow company, which was registered in 1883 as the Cassel Gold Extracting Company to acquire certain patent rights of Mr. H. R. Cassel for an improved method of extracting gold from ores. The company changed its title in 1906, and confined its business to the manufacture of cyanide. The directors are Col. Sir Ed. A. Brotherton, Bart., LL.D. (chairman), A. Moore, C.A., J. A. Spens, LL.D., Wm. Neill (managing), H. N. Beilby, T. Ewan, M.Sc., Ph.D., F.I.C., J. L. Deuchar, B.A., LL.D.

W. J. BUSH AND CO., LTD.

The thirtieth annual general meeting was held on May 23. Mr. J. M. Bush (chairman and managing director) presiding. In view of the unsettled industrial conditions which prevailed during the past year, the results shown by the accounts were regarded as satisfactory. The high price of fuel enhanced materially the cost of the fine chemicals manufactured by the company, at a time when foreign competition was becoming increasingly severe. But against this the company had the benefit of more economic production through the use of its remodelled plant. The outlook indicated that foreign competition in fine chemicals would continue, and that profits in this field of work were not likely to be commensurate with the knowledge and skill required. But the manufacture of fine chemicals was only one section of the company's business. Its main foundation was based on the manufacture of flavouring essences and the distillation of and trading in essential oils, and in this direction an upward tendency in sales was shown, notwithstanding the decline in

turnover in some foreign markets. The subsidiary companies in New York and Montreal showed substantial profits. The net profit of the company for 1926 was £57,880, which with £53,544 brought forward, makes an available balance of £111,424. A final dividend of 7% was declared on the ordinary shares, making 10% for the year, absorbing £25,000; general reserve received £20,000, and £60,174 was carried forward.

CHLORIDE ELECTRICAL STORAGE CO.

A dividend has been declared of 5%, making 10% for 1926, together with a bonus of 2s. per share, both tax-free.

DUNLOP RUBBER CO., LTD.

The twenty-eighth ordinary general meeting, held on April 12, was presided over by the chairman, the Right Hon. Sir Eric Geddes, G.C.B., G.B.E. The fact that the company was able to show such highly satisfactory results, and was able to increase its dividend from 15% to 20%, in spite of the difficulties of the year, served as proof that its prospects were brighter than they had even been. The company had to be both progressive and highly efficient to meet competition with a product in which raw material representing 60% of its total cost was subject to violent fluctuations in value. In addition to sharing with other industries the havoc caused by the disturbances of 1926, the company had had to face a 29% drop in the average value of the main raw material, necessitating drastic writing down of its stocks. In addition, 1926 had been the worst tyre-buying year in the recent history of the automobile industry, but during the first three months of the current year sales have beaten all previous records. The Tire and Rubber Corporation of America, in which the company had a large investment, made a small profit on its operations after providing for full depreciation, and was considered to be making satisfactory progress. During 1926 the estates had supplied 80% rubber in excess of their output of the previous year, and very far in excess of the output of any group of estates in the British Empire. Referring to the Anode patents, these involved the electric deposition of rubber upon moulds by electrolysis, and were due to Dr. P. Klein. The licences to manufacture under these patents were offered to the company some time ago, and a small experimental plant had been installed, and the company was fully confirmed in its views as to their probable value and further development. It decided to acquire, in addition to the licence, an interest in the patents themselves, and a substantial interest had also been obtained in the Hungarian Rubber Company, which controls the patents outside the U.S.A.

AMERICAN CELLULOSE AND CHEMICAL MANUFACTURING CO.

A large increase in earnings is shown by the report for 1926, the net working profit being \$1,458,517, compared with \$305,360 for 1925. The directors have authorised the issue of 55,000 shares 7% cumulative first participating preferred and 13,750 shares of common stock in 13,750 blocks (each consisting of four shares of preferred and one share of common stock). These are to be offered to the common shareholders for subscription at \$450 for each block. This issue is to provide funds for the doubling of the company's factory, in order to supply the increasing demand for its products.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton. f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d. 2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Sal ammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate. 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic, Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Cerium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithophone, 30%.—£22 10s. per ton.
 Mmral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey. £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d. 4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carbolic.—Crystals.—8½d.—9d. per lb. Crude 60's, 2s. 4d. 2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. Steady. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%. 2s.—2s. 2d. per gal. Dark, 1s. 9d.—2s. 1d. per gal.
 Anthracene Paste.—A quality, 2½d. 3d. per unit, 40%—3d. per unit: Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons, Pure, 1s. 8d.—2s. 3d. per gal., ex works in tank wagons.
 Toluene.—90%, 1s. 9d.—2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol. 1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24°.—10½d. per gal. Standard specification, 6½d. 9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naptha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 10d. 1s. 11d. per gal. Solvent 95/160, 1s. 6d.—1s. 7d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Quiet. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol (disulpho (1.8.2.4.))—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7d. per lb., naked at works.
 Aniline Salts.—7d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline. 2s. 3d. per lb.
 Dimethylaniline. 1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene. 48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine. 3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 3d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xyldine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 4½d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s. 3d. per oz.; 500 oz. lots.—1s. per oz.
 Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 6½d.—1s. 7½d. per lb. Less 5%. Advancing.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic. B.P. 1s. 3½d.—1s. 5d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%. Firm market.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d. 3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.
 Bromides.—Ammonium.—2s. 3d.—2s. 4d. per lb. Potassium.—1s. 10d.—2s. per lb. Sodium.—2s. 1d.—2s. 2d. per lb. All spot.
 Calcium Lactate.—1s. 4d.—1s. 5d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ether meth.—1s. 1d.—1s. 11½d., per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacum Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green. 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—22s. per cwt., 112 lb. lots.
 Magnesium Carbonate.—Light Commercial £31 per ton net.
 Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%, in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 11s.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonate.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin. 3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar) 100s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferriyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17s. 2d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb. Very limited inquiry.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C. 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.
 Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
 Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
 Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
 Sulphonol.—7s. 6d. per lb.
 Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.
 Thymol, Puriss.—11s.—12s. per lb., according to quantity.
 Natural.—13s. 6d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
 Aubepine (*ex Anethole*).—10s. 6d. per lb.
 Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb.
 Amyl Salicylate.—3s. per lb.
 Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
 Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb.
 Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 3d. per lb.
 Cinnamic Aldehyde.—Natural, 17s. per lb.
 Coumarin.—10s. 6d. per lb.
 Citronellol.—14s. 6d. per lb.
 Citral.—8s. 3d. per lb.
 Ethyl Cinnamate.—10s. per lb.
 Ethyl Phthalate.—2s. 9d. per lb.
 Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol. 6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb. (*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb. (*ex Shui Oil*) 14s. 6d. per lb.
 Methyl Anthranilate.—8s. 6d. per lb.
 Methyl Benzoate.—4s. 6d. per lb.
 Musk Ketone.—35s. per lb.
 Musk Xylol.—8s. 6d. per lb.
 Nerolin.—3s. 9d. per lb.
 Phenyl Ethyl Acetate.—12s. per lb.
 Phenyl Ethyl Alcohol.—9s. 9d. per lb.
 Rhodinol.—30s. per lb. Saffrol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanilin.—17s.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—14s. 9d. per lb.
 Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%. 8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure.—6s. per lb.
 Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 9d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 15s. 6d. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The Complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 18th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on June 2nd. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

Applications

Arnold (Standard Development Co.). Lubricants. 12,473. May 9.
 Bacher. Heat-exchange apparatus. 12,438. May 9. Austria, 7.5.26.)

Buttner-Werke, and Kleinmann. Decolorising agents. 13,023. May 14.

Crowe. Grinding and separating apparatus. 12,702. May 11.

Neill. Crushing etc. machines. 12,779. May 12.

I.—Complete Specifications

7794 (1926). Alliot, Hatfield, and Achille Serre, Ltd. Filtration. (270,461.)

8201 (1926). Torrance. Grinding mills. (270,465.)

14,035 (1926). Marston. Rotary drying apparatus. (270,503.)

16,903 (1926). Carborundum Co., Ltd. (Johnson). Kilns. (270,520.)

29,997 (1926). Ultra-Filtre. Purification, decoloration, and deodorisation of liquids and solutions. (262,131.)

30,978 (1926). Grimason, and Keesbey-Mattison, Ltd. Heat-retaining coverings or lagging. (270,589.)

5146 (1927). Haddan (Oliver Continuous Filter Co.). Pulp thickeners or filters. (270,616.)

*11,871 (1927). Power Specialty Co. Fractionating tower. (270,720.)

*12,438 (1927). Bacher. Heat-exchange apparatus. (270,759.)

II.—Applications

Akt. Separator, and Steward. 12,789. See III.

Bunge and Pistorius. Splitting coal into its constituents. 12,919. May 13. (Ger., 8.9.26.)

Cross. Making motor fuel. 12,773. May 12. (U.S., 28.6.26.)

I.-G. Farbenind. Transforming hydrocarbons. 12,402. May 9. (Ger., 20.5.26.) Production of hydrocarbons.

12,403. May 9. (Ger., 22.5.26.) Extraction of carbon dioxide from gaseous mixtures. 12,404. May 9. (Ger., 28.5.26.)

Production of valuable liquid etc. from coal etc. 12,680—5. May 11. Production of hydrocarbons from natural oils etc. 12,777—8. May 12.

Mathys (Tar and Petroleum Process Co.). Coke ovens. 12,642. May 11.

N.V. Silica en Ovenbouw Mij. Coke ovens. 12,461. May 9. (Ger., 8.5.26.)

Rhenania-Kunheim Ver. Chem. Fabr. Apparatus for roasting gas-purifying substances. 12,771. May 12. (Ger., 25.5.26.)

Simon Extracting Machine Syndicate, Ltd., and Simon. Apparatus for refining oils. 12,653. May 11.

Still. Coke ovens. 12,795. May 12.

Whitfield. Production of gas from solid fuel. 12,354. May 8.

II.—Complete Specifications

4122 (1926). Patent Retorts, Ltd., and Davidson. Gas generators. (270,429.)

4323 (1926). Katz. Apparatus for quantitative determination of gases. (249,088.)

14,181 (1926). Threlfall. Manufacture of activated carbon. (270,505.)

23,416 (1926). Geipert. Distilling small samples of coal. (267,082.)

*21,749 (1926). Standard Development Co. Treating sulphur-containing oils. (270,626.)

*9282 (1927). American Hydrocarbon Co., Inc. Apparatus for extracting vaporisable matter from fragmentary solid materials and the like. (270,662.)

*11,569 (1927). I.-G. Farbenind. Conversion of coal materials into valuable liquid products. (270,698.)

*11,656—7 (1927). I.-G. Farbenind. Pulverulent fuel for internal-combustion engines. (270,702—3.)

*11,658 (1927). I.-G. Farbenind. Conversion of hydrocarbons of high boiling-point into others of lower boiling-point. (270,704.)

*11,650 (1927). I.-G. Farbenind. Manufacture of hydrocarbons. (270,705.)

*12,401 (1927). N.V. Silica en Ovenbouw Mij. Coke ovens. (270,765.)

III.—Application

Akt. Separator, and Steward. Dehydration of water-gas tar emulsions. 12,789. May 12.

IV.—Applications

Carpmael (I.-G. Farbenind.). Manufacture of derivatives etc. of anthraquinone. 12,808. May 12. Manufacture of vat dyestuffs. 12,809 and 13,024. May 12 and 14.

I.-G. Farbenind. Production of azo dyestuffs. 12,668. May 11. (Ger., 11.5.26.)

IV.—Complete Specifications

4096 (1926). British Dyestuffs Corp., Baddiley, and Hill. Azo-dyestuffs and process of dyeing acetyl cellulose. (270,428.)

5288 (1926). British Dyestuffs Corp., Baddiley, Chorley, and Brightman. Manufacture of new azo dyes and process of dyeing. (270,446.)

32,840 (1926). I.-G. Farbenind. Manufacture of alkyl-naphthalenes chlorinated in the nucleus. (263,844.)

*12,294 (1927). I.-G. Farbenind. See XIII.

V.—Applications

Bleachers Association, Ltd., Barrett, Kershaw, Sutton, and Whitelegg. Treatment of cellulosic materials. 12,345—8. May 9.

Dreaper. Artificial silk etc. 12,591. May 11. Manufacture of cellulose esters. 12,713. May 12.

Inray (I.-G. Farbenind.). Manufacture of mixed acid esters of cellulose. 12,794. May 12.

Nobel's Explosives Co., Ltd., and Traill. Manufacture of cellulose compounds. 12,664. May 11.

Nobel's Explosives Co., Ltd., Traill, and Wilson. Cellulose compounds. 13,022. May 11.

V.—Complete Specifications

27,721 (1925). Clavel. Treatment of cellulose ester materials. (252,661.)

2439 (1926). Heberlein. Treatment of cellulosic material (270,375.)

7061 (1926). Scholz. Manufacturing cuprammonium silk threads. (249,845.)

8917 (1926). I.-G. Farbenind. Preparing hair for felting. (250,575.)

*8170 (1927). Soc. Chim. Usines du Rhône. Continuous manufacture of cellulose acetate. (270,656.)

VI.—Applications

Böhm. Dyeing-apparatus. 12,437. May 9. (Austria, 7.5.26.)

Chem. Fabr. vorm. Sandoz. Preparation of effect threads. 12,822. May 12. (Ger., 13.10.26.)

Sindl. Apparatus for wet treatment of textile fibres etc. 12,646. May 11. (Ger., 7.2.27.)

VI.—Complete Specifications

3558 (1926). I.-G. Farbenind. Dyeing mixed textile goods. (247,224.)

4096 (1926). British Dyestuffs Corp., Baddiley, and Hill. See IV.

5091 (1926). I.-G. Farbenind. Reserving animal fibres. (248,007.)

5288 (1926). British Dyestuffs Corp., Baddiley, Chorley, and Brightman. See IV.

*32,851 (1926). Kritchewsky and Prutsman. Chemicals for colouring fabrics. (270,637.)

*8270 (1927). Soc. Anon. Etabl. Petitdidier. Colour-printing on fabrics having a foundation of silk or wool. (270,657.)

*12,437 (1927). Böhm. Dyeing apparatus. (270,758.)

VII.—Applications

Fairlie, and Fairlie & Co., Ltd. Manufacture of chromates of potash etc. 12,783. May 12.

I.-G. Farbenind. 12,404. See II. Production of chromates. 12,772. May 12. (Ger., 1.7.26.)

Titan Co. Akt. Manufacture of titanium compounds. 12,656. May 11. (Norway, 12.5.26.)

VII.—Complete Specifications

3565 (1926). Uhde. Synthetically producing ammonia. (247,225.)

10,451 (1926). Harnist. Manufacture of ammonium sulphate and bisulphate and of sulphur. (250,990.)

24,214 (1926). Uhde. Synthetic production of ammonia. (259,230.)

24,609 (1926). Falco. Manufacture of baryum salts free from sulphur. (270,559.)

30,568 (1926). I.-G. Farbenind. Manufacture of phosphorous acids and hydrogen. (262,447.)

*8894 (1927). Colombo. Chambers for the manufacture of sulphuric acid. (270,661.)

*11,805 (1927). Permutit A.-G. Production of chromyl chloride. (270,711.)

IX.—Applications

Bates. Artificial marble. 12,895. May 13.

Consortium f. Elektrochem. Ind. Cementing, impregnating, etc. 12,669. May 11. (Ger., 11.5.26.)

Harnisch. Artificial stone. 12,949. May 13. (Ger., 14.5.26.)

Rigby. Manufacture of cement. 12,470. May 9.

Thompson. Manufacture of bricks etc. 12,614. May 11.

IX.—Complete Specifications

27,558 and 28,569 (1925). Rigby. Treatment of slurries in rotary kilns. (270,356.)

12,826 (1926). Voisin. Manufacture of aluminous cements (270,496.)

*6375 (1927). Alexander. Manufacturing bituminous products. (270,649.)

X.—Applications

Buhrmann. Superheating blast furnace etc. slag. 12,662. May 11. (Ger., 15.5.26.)

Copper Deoxidation Corp. Refining etc. copper. 12,435. May 9. (U.S., 26.5.26.)

Dechesne. Apparatus for purifying etc. molten metals. 12,876. May 13. (Ger., 14.5.26.)

Garnett, Holden, and Smith. Magnetic alloys. 12,934. May 13.

Harris. Production of metals. 12,471. May 9.

I.-G. Farbenind. Manufacture of highly-porous coherent lead aggregates. 12,459. May 9. (Ger., 7.5.26.)

Michel. Metallurgy of magnesium etc. 12,665. May 11. (Fr., 11.5.26.)

Siemens & Halske A.-G. Copper-beryllium alloys. 12,454. May 9. (Ger., 21.5.26.)

X.—Complete Specifications

6662 (1926). Smith. Soldering aluminium. (270,453.)

22,249 (1926). Dwight & Lloyd Metallurgical Co. Sintering machines. (264,450.)

23,385 (1926). Kelly. Alloys. (270,553.)

31,283 (1926). Meyer and Meyer. Recovering antimony from alloys. (264,139.)

*1282 (1927). Kropf. Alloys of high melting-point. (270,640.)

*11,035—6 (1927). Parker Rust Proof Co. Rust-proofing (270,679—80.)

*12,132 (1927). Schwarz. Working-up mixed shavings of white metal and red metal. (270,740.)

*12,459 (1927). I.-G. Farbenind. Manufacture of highly porous coherent lead aggregates. (270,763.)

XI.—Applications

Anglo Galvanising Co., Ltd., and Charlier. Manufacture of zinc electrolytes. 12,770. May 12.

Wilderman. Electric batteries. 12,564. May 10.

XI.—Complete Specifications

27,419 (1925). Ajax Electrothermic Corp. Induction furnaces. (243,694.)

27,420 (1925). Ajax Electrothermic Corp. Induction electric furnaces. (247,519.)

15,687 (1926). Mond (Warlimont). Preventing evaporation and oxidation of heated electrolytes. (270,514.)

23,063 (1926). Langbein-Pfanhauser-Werke A.-G. Galvanic mass production. (266,285.)

28,048 (1926). Comp. Franc. pour L'Exploit. des Proc. Thomson-Houston. Primary voltaic cells. (261,371.)

217 (1927). Brown, Boveri, et Cie. Electrode carriers for electric furnaces. (264,157.)

*12,078 (1927). British Thomson-Houston Co., Ltd. Treating filaments. (270,733.)

XII. Applications

Arentz. Boilers for whale oil. 13,006. May 14. (Norway, 15.5.26.)

Simon Extracting Machine Syndicate, Ltd., and Simon. 12,653. See II.

XII.—Complete Specifications

3875 (1926). Cabot. Polymerisation of oils. (250,538.)

*11,964 (1927). British Thomson-Houston Co., Ltd. Oleaginous compositions. (270,724.)

XIII. Applications

Consortium f. Elektrochem. Ind. 12,669. See IX.

Marks (Bakelite Corp.). Condensation products. 12,914. May 13

XIII.—Complete Specifications

4466 (1926). Bakelite Ges. Production of compositions containing phenolaldehyde condensation products. (247,957.)

8888 (1926). Commercial Solvents Corp. Synthetic resins and their manufacture. (250,265.)

*7217 (1927). Sichel Kommandit Ges. Manufacture of a colour-binding means. (270,652.)

*8480 (1927). Comp. Lorraine de Charbons, Lampes, et App. Electriques. Treatment of pulverulent fillers and pigments. (270,658.)

*10,210 (1927). Chem. Fabr. (vorm. Schering). Printers' ink. (270,671.)

*11,035--6 (1927). Parker Rust Proof Co. See X.

*12,294 (1927). I.-G. Farbenind. Manufacture of colour lakes. (270,750.)

XIV. Application

Rubber Latex Research Corp. Rubber compositions. 13,038. May 14. (U.S., 1.6.26.)

XIV.—Complete Specifications

18,533 (1926). Simplex Wire & Cable Co. Rubber compounds. (269,124.)

23,346 (1926). Danier. Regeneration of rubber. (269,127.)

*4642 (1927). Silesia, Ver. Chem. Fabr. Accelerating vulcanisation. (270,644.)

*10,659 (1927). Scheithauer. Regenerating rubber. (270,675.)

XV. Application

I. G. Farbenind. 12,457. See XXI.

XVI.—Application

Patton. Insecticide for red spider. 12,513. May 10.

XVII.—Application

Dorr Co. Carbonation of sugar juices. 12,436. May 9. (U.S., 8.5.26.)

XVII.—Complete Specification

12,436 (1927). Dorr Co. Continuous carbonation of sugar juices. (270,757.)

XIX.—Application

Landé. Flour improver etc. 12,812. May 12.

XIX.—Complete Specifications

14,746 (1926). To Aroha Dairy Co., Ltd., and Murray. Deodorising fluids. (270,509.)

25,420 (1926). Beaufour. Extraction of albuminaceousness of vegetable origin. (260,242.)

*11,660 (1927). Treuhand-Ges. Bartmann & Co. Treatment of cereals. (270,706.)

XX.—Applications

Consortium f. Elektrochem. Ind. Manufacture of butyric aldehyde. 12,907. May 13. (Ger., 15.5.26.)

Dicker (Verein f. Chem. Ind.). Production of santalol derivatives. 12.8.11. May 12.

Elektrizitätswerk Lonza. Manufacture of crotonaldehyde. 12,460. May 9. (Switz., 8.5.26.)

XX. Complete Specifications

2300 (1926). U.S. Industrial Alcohol Co. Esterification. (246,526.)

4302 (1926). Carpmuel (I.-G. Farbenind.). Manufacture of condensation products of crotonaldehyde. (270,433.)

25,400 (1926). Consort. f. Elektrochem. Ind. Manufacture of acetals. (264,791.)

26,754 (1926). Consort. f. Elektrochem. Ind. Manufacture of acetaldehyde. (260,305.)

31,612 (1926). Binz and Rath. Production of 2-oxy-3-bromopyridine-5-arsinic acid. (263,142.)

3721 (1927). Merck, Merck, Merck, Merck, and Merck. Dehydrating ethyl alcohol. (270,612.)

*6540 (1927). Canadian Electro Products Co. Manufacture of benzoic acid esters. (270,651.)

*11,998 (1927). Chem. Fabr. (vorm. Schering). Manufacture of derivatives of aminometal-mercaptosulphonic acids and salts thereof. (270,729.)

*12,460 (1927). Elektrizitätswerk Lonza. Manufacture of crotonaldehyde. (270,764.)

XXI. Applications

Chem. Fabr. vorm. Schering. Photographic gelatin papers. 12,935. May 13. (Ger., 14.5.26.)

I.-G. Farbenind. Gelatin for light-sensitive silver salts emulsions. 12,457. May 9. (Ger., 16.6.26.)

XXI.—Complete Specifications

3263 (1926). Wade (Wadsworth Watch Case Co.). Photographic processes. (270,386.)

3264 (1926). Wade (Wadsworth Watch Case Co.). Manufacture of photographic media. (270,387.)

XXIII.—Application

Bourgognion and Philips. Treatment of water. 12,542. May 10. (Holland, 11.5.26.)

XXIII. Complete Specifications

4920 (1926). Walker, Ltd., and Freestone. Manufacture of disinfecting, deodorising, or sanitising substances. (270,440.)

9561 (1926). Walker, Ltd., and Freestone. Insecticide. (270,470.)

14,746 (1926). To Aroha Dairy Co., Ltd., and Murray. See XIX.

29,997 (1926). Ultra-Filtre. See I.

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Chinaware, glassware, cutlery (445). *British India*: Paint, varnish, soap (497);

Galvanised-iron wire (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1); Cast iron, rolled steel (Directors, South Indian Railway Company, Ltd., 91, Petty France, London, S.W.1). *Canada*: Malt extract (498); Metal sheets, steel, brass, copper, tinplate (501); Aluminium hollow-ware (504). *Egypt*: Stone-crushing machinery, manganese steel, special steel, forgings, iron and steel castings (513). *Germany*: Artificial silk yarns (505); Ores, metals, chemical and pharmaceutical products (506). *Spain*: Galvanized-iron sheets, galvanized hoop iron (511). *Sweden*: Rubber goods, linoleum, oilcloth (512). *Turkey*: Galvanized iron wire, solder, lead, tin (A.X. 1689).

New Coke-oven Plant

The Nunnery Colliery Company, of Sheffield, has placed an order with the Woodall Duckham Vertical Retort & Oven Construction Company (1920), Ltd., for a complete coke-oven works, comprising a battery of 25 Becker ovens capable of carbonising 3600-tons of slack per week. The contract includes the erection of semi-direct by-product recovery plant, railway sidings, coal store, coal- and coke-handling plant, and coke-screening plant.

New Dyestuffs

The latest addition to the British Dyestuffs Corporation range of vat colours is Durindone Scarlet Y Paste, which, on account of its brilliant shade, is of considerable interest to the calico printing trade, either for direct printing, tannin discharge style, or discharging by the Rongalite-Leucotrope process. It is applicable to all forms of cotton materials where brilliancy of shade, cross-dyeing and chlorine fastness is required. In particular, it is very suitable for the dyeing of cotton yarns fast to washing. It is also very suitable for wool dyeing where particular fastness to milling is required, and possesses the additional advantage of vatting in the presence of ammonia without the addition of caustic soda. It is of interest for the dyeing of viscose artificial silk, giving even shades on material of irregular quality.

News from Advertisements

Copies of the JOURNAL OF THE SOCIETY OF CHEMICAL INDUSTRY are offered for sale (p. viii).

Research Assistant required for Government Laboratory (p. viii).

Applications are invited from ex-service men between the ages of 23 and 30 for certain posts of Class II chemists in the Establishment of the War Department Chemist at Woolwich (p. viii).

Safeguarding of Key Industries

The Board of Trade give notice that representations have been made to them under Section 10 (5) of the Finance Act, 1926, for the exemption from a Safeguarding duty of the following articles: Didial (ethyl morphine diallyl barbiturate); ethylene glycol, and glycol ethers.

Communications regarding the application should be addressed to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George Street, S.W.1, within two months from the date of this notice (May 18, 1927).

EDITORIAL

The Geneva Conference

THE Final Report of the World Economic Conference is an interesting document of fifty pages; its conclusions are mainly very general statements of the best methods of persuading the nations of Europe to become more peaceful, more economical, and more prosperous. So far as international commerce is concerned, it advocates free trade and deprecates dumping. The Report adopts that cautious and general tone in dealing with the great European problems which is characteristic of the editorials which have often appeared in these columns. The Report does, however, speak with greater authority, though hardly with greater precision. The President's address to the Conference and the subsequent pages of the Report would be even more impressive if we knew who the President was and who were the individuals who have published these words of wisdom; this omission from the document should be remedied when it is republished. So far as Great Britain is concerned, we know that Sir Arthur Balfour, Mr. Walter Runciman, Mr. W. T. Layton, Sir Norman Hill, Sir Max Muspratt, Mr. Arthur Pugh, Sir Hubert Llewellyn Smith, and Mr. W. J. U. Woolcock were included in the delegation; if other countries were as strongly represented as Great Britain the Report of the Conference should carry very great weight. We had the opportunity a few years ago of attending two international conferences, one at Washington and one at Geneva. In those days two hundred and fifty people from fifty different countries met, usually for the first time; nine-tenths of them did not trust each other, three-quarters of them did not understand each other. After the lapse of a fortnight or three weeks they came to the conclusion that most of them were sensible and able men, sincerely anxious to be useful and helpful. A few general principles were stated and hotly debated, many impracticable suggestions and inexpedient phrases were at the last moment unanimously excluded, and just as we had got to know something of each other and the many subjects we were discussing we had to go home to attend to our business. We hope that things have now altered for the better in these international conferences. The Final Report is well worth reading, and costs one shilling. Special memoranda have been prepared on the chemical industry, the potash industry, and the artificial silk industry.

The Annual Meeting in Edinburgh

It is difficult to think of any city so well suited to an annual meeting of a learned society as Edinburgh. We have seen many northern cities which

are now, or once were, capitals of small or large kingdoms; few of them can compare with Edinburgh in beauty and historic interest. Its history goes back some thirteen hundred years, and it has many monuments remaining of the Middle Ages. Its streets constantly remind us of John Knox, of Sir Walter Scott, of the great family of the Sturmts, and of those many famous men who flourished in Edinburgh in the nineteenth century. To the historian and to the geologist the whole district is fascinating; we see no reason why it should not be fascinating to the chemist. Certainly the Edinburgh Section has provided a programme which is remarkably attractive. One kindred society, the Biochemical, has arranged interesting matter for our consideration, and the Society is duly grateful; two branches of the Society, the Engineering Group and the Fuel Section, have also contributed valuable papers for serious chemists. The presidential address on Tuesday, July 5, is sure to be good, and we feel equally confident about the address of the Messel Medallist, Col. Pollitt, fixed for the Thursday. Let no one say the Society does not pay due attention to the eternal verities: those who hear all the papers will for ever after be wiser and better-informed than their fellow creatures; moreover, they will have, in addition to their immediate pleasure and subsequent justifiable self-satisfaction, a gratification of another sort. Those who listen to the President's address will be panoramically photographed; those who pay due attention to Col. Pollitt's remarks on synthetic ammonia will be received in the evening by the Lord Provost and magistrates. The social side of these annual meetings is, as has often been remarked, of considerable educational value: if you wish to know about a man, dance with his wife, or play bridge with his aunt, neglect not these simple hints; if you find your daughter taking your chief chemist out in your Rolls-Royce, the two-seater, your opinion of him cannot remain as it was. You may learn how to raise the cardiac temperature at Dryburgh Abbey on a sunny afternoon or at Melrose in the pale moonlight, a sort of fuel economy amounting almost to a science; if you wish to learn the most recent facts of biochemistry, you must lure Prof. Drummond or Dr. Dudley to see an inspection of the Black Watch at the Castle or to view the Raeburns in the National Gallery. In an unguarded moment either of these may reveal the very fact you are waiting for. As for the lunch and the dinner, we advise our English friends to reflect on the changes which time has brought about; it is no longer safe to assume that if after dinner you find the table is some two feet vertically above you, necessarily there will

be found a wee laddie detailed to loosen your cravat—it was so in the old days, no doubt. The view from the top of Scott's Monument is wonderful: we advise the young and incredulous to verify this statement; others may take our word for this, and everything else we say, in perfect confidence. As for Abbotsford, those who have once been there have never forgotten it. Peebles we cannot discuss; we never visited it. On the other hand, the great law case of *Peebles v Plainstones* is familiar to us, and whilst in Edinburgh we shall, no doubt, revisit some of the scenes with which it is connected. We think we have sufficiently indicated our belief that in scientific importance, in social activity, in the enjoyment of Scots hospitality, and in the provision of gaseous, spiritual, liquid and solid matter, this forthcoming gathering at Edinburgh will be unsurpassed. We intended to conclude this notice with an account of the geology of Arthur's Seat and North Berwick law, but this has belahps been already better done by Geikie.

The Livesey Professor at Leeds

Prof. J. W. Cobb has prepared a report of the work of his Gas and Fuel Department at Leeds during the sessions 1924—5 and 1925—6. We recollect very well the Leeds University long before a Gas and Fuel Department was dreamed of, and we well knew Prof. Cobb long before he dreamed of becoming a Fuel Professor there, or anywhere else. We recollect also that when the department was created it seemed to us to be a subject entirely unfitted for any University curriculum. Without any sense of shame, we now admit that the study of fuel is so vast and so important as to deserve great attention, and we can think of no better way of training up research workers in connexion with fuel than the way of the department at Leeds and under the direction of Prof. Cobb. You must train up your men before they can undertake research; without proper research, no progress in fuel will be worth bothering about. The West Yorkshire Coal Owners' Association has again come to the assistance of the Fuel Department at Leeds by the handsome donation of £25,000 towards an extension of the premises, and no doubt this will enable a greater quantity of research to be carried out. Prof. Cobb's department is a wide one, for it includes not only coal gas and fuel, but also refractory materials and metallurgy; consequently, the recent researches cover a wide area, the influence of ash constituents on carbonisation, the gasification of coke in steam, the scaling of metals, the removal of sulphur compounds from coal gas by catalysis, the properties of sillimanite and the recrystallisation of metals. The technology of fuel has made remarkable advances in recent years; many of us remember the introduction of the internal-combustion engine, of oil as a fuel, of low-temperature carbonisation, of the direct contact of water with flame or explosion as in the Brunler boiler and the Humphrey pump, of powdered coal as a fuel, of the incandescent mantle and the change of gas from a lighter to a heater, of superheaters and steam accumulators, of the hydrogenation of coal. Who will say that we have not made great progress, and that we shall not make much more if we study fuel as they do at Leeds?

TESTING OF SEPARATORS FOR ACCUMULATORS

By M. WILDERMAN, Ph.D., B.Sc.

THE ELECTRICAL RESISTANCE

This is important for the determination of the variation of the volts with temperature, and of the difference in the volts obtained with different separators having different resistances, when different ampere discharges are made (see CHEM. AND IND., January 21, 1927, p. 55).

This is determined by the method of Kohlrausch. The electrical resistance of the solution between two platinised platinum electrodes is measured first without any separator, then with the separator. This gives the increased resistance due to the separator, which can be expressed in millimetres of solution at a given temperature. The temperature coefficient is then determined. The resistance is measured after 5 min., 10 min., some hours, and then days till the minimum resistance is reached.

This gives the initial resistance of the separator and how soon its best working conditions are attained. The separator ought to be tested dry and when moist, as upon this depends its usefulness.

Perforated ebonite sheets do not even give their minimum resistance at once, evidently on account of the air which gets entrapped in the holes between the solution. For example, with a section of a perforated ebonite separator 11.7 cm.² by 0.5 mm. thick, with holes 1.5 mm. diameter the resistance introduced was:

1st day	2nd day	3rd day	4th day	5th day	8th day
Ohms.	Ohms.	Ohms.	Ohms.	Ohms.	Ohms.
0.300	0.248	0.187	0.134	0.061	0.056

The minimum value should be 0.014 ohm.

SPEED OF ABSORPTION OF THE SOLUTION BY THE SEPARATOR

This is determined by dipping the separator perpendicularly into a flat dish of water to a depth of 1 cm. of the diaphragm and measuring the time taken for the solution to reach different heights of the diaphragm by absorption. This property in the separator is important for hot countries, where batteries are liable to get dry.

The property of absorption also explains the enormous differences in the time taken for a separator to reach its minimum resistance.

THE SPEED OF PERCOLATION

This is important for the determination of the speed of circulation of the electrolyte between the electrodes. This is done by taking a given disc of the diaphragm of a given uniform thickness (say 1 mm.), fixing it in a small cylinder by means of rubber rings (see Fig. 1) so that the solution from the cylinder can only pass through the diaphragm. The cylinder is connected with a glass tube of a given height, which is connected at the top to a vessel or small tank where water is run in and kept at a constant level by a suitable overflow pipe, thus ensuring a constant height of water (say 1 metre) on the diaphragm under test.

The speed of percolation of water through a porous diaphragm is :—

$$V = \frac{KSP}{L}$$

V = amount of water passing through a diaphragm per 1 cm.² per minute.

S is the surface of diaphragm expressed in cm.²

P is the height of the column of water pressing on the diaphragm expressed in cm.

L is the thickness of the diaphragm in mm.

K is the characteristic constant for the given diaphragm depending upon its nature, the radius of the capillaries and the viscosity of the solution which changes with temperature.

K = V when S = 1, P = 1, L = 1.

Then K gives the amount of water passing through a given diaphragm of 1 cm. square surface, 1 mm. thick

FIG. 1.

under a pressure of water of 1 cm. height per minute. If the same liquid, say water, of the same temperature be used for the diaphragms which are to be compared, the relative values of the characteristic constants K for the two diaphragms remain the same.

A rough and quick qualitative test of the speed of percolation can be made by letting a drop of water fall on the diaphragm and noting the speed of percolation to the other side. With the Wilderman porous ebonite separator it is instantaneous, whereas wood and other diaphragms remain practically unaffected.

Upon the speed of percolation depends the circulation of the solution between the electrodes, and upon this all the functions of the battery depend, during the discharge, such as the volta, ampere and watt hours capacity, speed of recuperation, etc. Upon the speed of percolation depends whether the separator can be used dry, or must be used wet, and whether a dry battery can be made and transported.

ESTIMATION OF THE RELATIVE AMOUNT OF SOLUTION CIRCULATING BETWEEN THE ELECTRODES DURING CHARGE AND DISCHARGE, USING DIFFERENT SEPARATORS

The equation given above enables us to approximately calculate the amount of solution passing per minute between the electrodes through 1 cm.² of the separator when different separators of varying construction are used. This is done by using the characteristic constant K for the given diaphragm as given above, and by inserting the actual values of P into the above equation.

In the battery only very small over-pressures (maximum 0.3 to 3 cm. of water) come into consideration (see article before mentioned) if the concentration of the solution is arranged to be different at each side of the diaphragm during charge and discharge. Having thus found the amount of solution passing through 1 cm.² of the diaphragm per minute, and knowing the total surface of the porous parts of all the separators used in the battery, we then get the total amount of the solution passing through all the diaphragms per minute. This is then compared with the total amount of the solution between the electrodes, as well as with the total amount of the solution in the battery. This shows whether the amount of solution passing through the diaphragm is sufficient to cause a circulation.

It should be noted :—

(a) If separators of perforated sheets be used, no electro-osmotic or hydrostatic pressures are present. In this case, P in the above equation equals zero, V equals zero; i.e., no circulation takes place.

(b) When a diaphragm is used with the solution between the electrodes equally divided, the number of molecules of the acid which are taken from the solution or pass into it during discharge and charge in unit of time being on both sides of the diaphragm equal, the concentration of the acids on both sides of the diaphragm is also equal; no hydrostatic pressure exists here, whilst the small electro-osmotic pressure still remains.

(c) When a diaphragm is used with the solutions between the electrodes unequally divided (more solution being on the positive than on the negative side), the concentration of the solution on the positive side is greater during discharge than on the negative side. An increased electro-osmotic and a hydrostatic pressure is then created from the positive side to the negative side of the diaphragms through it, and can only be approximately estimated by taking into account the value of the specific gravity of the solution on each side of the diaphragm during discharge and the height of the electrodes.

TESTING ACCUMULATORS

In making comparative tests with different kinds of separators such as wooden separators having no frames or vertical supports, and threaded rubber separators having vertical ebonite strips or Wilderman separators, having a frame and vertical ribs etc., it is essential that equal active surfaces of the electrodes should work in all cases. If the cell is to work to the best advantage it is necessary that the electrode should be adapted to the separator, or the separator to the electrode, both giving

the same active surface. It is just as important that the electrodes should have a longer life as it is to prolong the life of the separator. The principle involved in the new ebonite separator consists in the provision of a non-compressible frame with vertical ribs (see patent No. 245,552, 1926) in order efficiently to support the outer frame and the corresponding vertical ribs of the grid of the electrode in a vertical and horizontal direction, thus forming one solid block preventing the electrode from buckling and bending in any direction.

With threaded rubber separators the electrodes should be constructed with corresponding strengthening ribs in the grid. The electrodes are then much stronger and can be made thinner, *i.e.*, a battery of greater active surface capacity can be made for the same weight.

If the electrode be not adapted to the Wilderman separator, the separator is then made with a non-compressible frame with porous vertical ribs instead of non-porous, to suit the given electrode. If the separators and electrodes are not adapted to one another, and different separators be compared, the same active surfaces of the electrodes should be taken for test in both cases, by inserting an insulating ebonite sheet of the requisite surface between the outer negative and positive electrodes.

Before any two batteries with the same or different kinds of electrodes can be used for the testing of the comparative merits of two different kinds of separators, it is necessary that, with the same active surfaces of the electrodes, their volts, ampere and watt-hours capacity when discharged without separators between the same equipotential lines, the concentration of the acid, its temperature and the distance between the electrodes, be the same in both batteries, thus eliminating all factors other than the physical factors of the different separators. For this a number of new cells, which are supposed to be of the same capacity, with glass rods of the desired diameter (say, 2½ mm.) between the electrodes, are taken and first charged in series with the same current until they all reach the same total potential of 2.6 volts, the same single potentials (Cd. neg. and Cd. pos. readings), while the concentration of the acid and its temperature are kept the same. Readings are noted from time to time of the volts, single potentials, concentration, etc. As soon as one cell reaches 2.6 volts it is removed from the series and the other cells are further charged until they reach the same 2.6 volts at the same or at different times. The cells having all reached 2.6 volts are then all connected again in series and further charged for a couple of hours and all data noted. The cells are allowed to stand for about 12 to 24 hrs. in open circuit and the total volts, single potentials, etc. are again noted. It will be found that the volts have dropped very considerably. The cells are then discharged in series down to 1.8 or 1.7 volts with, say, 20 amperes for a 60-ampere-hour battery, a current which is not too great to bend or buckle the electrodes unsupported by separators. The volts, single potentials, amperes and time, etc. are noted from time to time during discharge. We thus get the discharge curves for the different cells. It will be found that the volts of the different cells and the discharge curves between equipotential lines are not the same. This will be due to the different capacities of

the electrodes, if the concentration of the acid, its temperature, and the distance between the electrodes are the same. It may, however, be found that between a number of such cells two or more show exactly the same drop of the volts, the same ampere and watt-hour capacity between the same equipotential lines. These are separated from the rest to be used for further tests. The chosen cells are charged again in series as before until they reach the same total volts, single potentials, etc. If the cells are of equal capacity they ought to reach the same volts in the same time, *i.e.*, the charge curves should practically coincide. A second discharge with 20, 30 or 40 amperes is made and the discharge curves noted. The cells which give the same charge and discharge curves are separated from the rest and used for testing the separators. The cells mentioned above are now again charged to about 2.3 volts, the glass rods removed, the two different kinds of separators placed in the batteries, and the cells further charged until they reach 2.6 or 2.65 volts.

The cells are then allowed to stand as before in open circuit, readings being taken and noted. A discharge is then made either in series or separately with the same amperes (10, 20 or 40 for a battery of 60 ampere hours, which gives the limit of the currents used for continuous work). If the circulation has an effect upon the volts, ampere hours, etc. of the battery, it will be found that the cells do not behave equally. If the cells are discharged in series it will be found that before one of the cells reaches, say, 1.8 volts, the volts of the other drop very considerably, although the discharge was made with the same amperes and the same time. If both cells are discharged separately down to the same 1.8 volts, it will be found that they reach these values at different times. In this case we get the drop in the volts, the ampere and watt-hours taken out between the same equipotential lines with the different separators. The cells are then allowed to stand in open circuit and the *recuperation* curves for both cells investigated, *i.e.* the speed of the rise of the volts in dependence of time is noted in both cases (Fig. 2). This is continued until they both reach their constant values. After this a second discharge in series (or separately) is made down to the same 1.8 volts as before. The second recuperation is then investigated, after which a third discharge is made down to the same volts.

The cells are now charged again. It is essential for correct work that if the cells were discharged separately the extra ampere hours which were taken out from one cell in comparison with the other should be returned to the cell, account being also taken of the efficiency of the cell during discharge, the object being to return to the cell the extra energy which was previously taken out from it, and to bring them both back as far as practicable to the same condition. The two cells are then charged in series again until both reach 2.6 (or 2.65) volts, and if one cell reaches 2.6 volts before the other it should not be disconnected, but should continue to be charged until the second cell in series also reaches 2.6 volts (as volt measurement alone does not give the capacity created by the charge).

After this, discharges with 100, 200 and 300 amperes are made, but only for comparatively short periods,

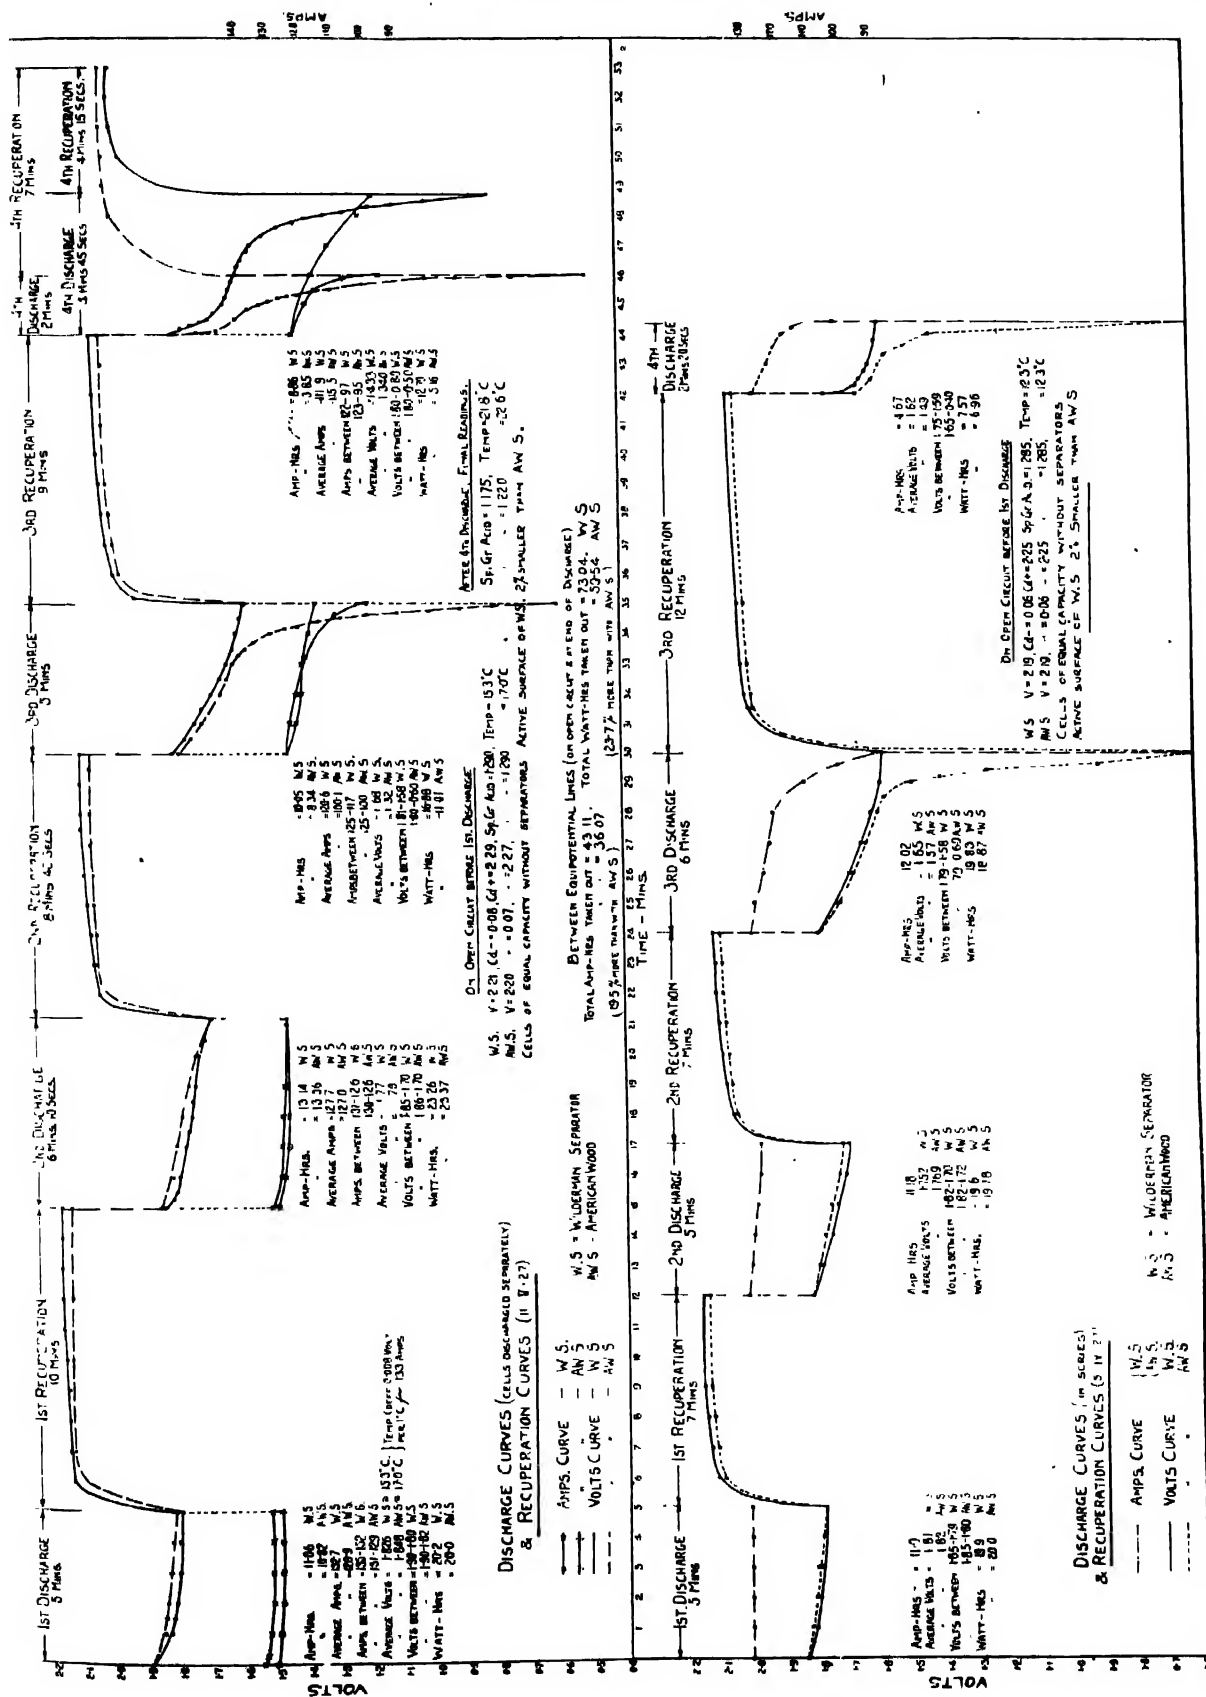

Fig. 2.

such discharges being used for starting a motor-car, in practice, usually for only a few seconds or a fraction of a minute. These discharges are made down to lower volts than 1.8, the initial volts of the same cells being, for physical reasons, given, in the above-mentioned article, lower when higher currents of discharge are used (see Fig. 2).

In making discharges of 100 amperes, either in series or separately, conduct the first discharge for five minutes, then allow it to recuperate for ten or fifteen minutes, and make a second discharge for five minutes, after which a second recuperation and a third discharge follows etc., until the volts reach a low value of about 1.3 volts. If the discharge of both cells is in series, it is stopped, if the volts in one of the cells reached about 1.3, even if the volts in the other cell is considerably higher.

The object of this procedure is to prevent damaging the batteries by an uninterrupted prolonged discharge, which, in view of the actual working of the batteries, does not come into consideration, and also in order to study the recuperation curves which are of great importance in the practical work of the battery. If the two cells are separately discharged with the same amperes down to the same volts, we have to proceed as before, returning the extra ampere hours taken out from one of the batteries, then charging again, until both reach in series the same 2.6 volts, when another discharge with, say, 150 to 200 amperes, is made with correspondingly shorter periods than five minutes, so as not to damage the batteries etc. Very short discharges with still higher amperes for a few seconds may be made.

CANADIAN MINERAL OUTPUT IN 1926

The total production of gypsum in Canada in 1926 amounted to 878,283 tons, compared with 740,323 tons in 1925. Imports of gypsum amounted to 6298 tons in 1926, as against 8921 tons in 1925, and Canadian crude gypsum exported, principally to the United States, totalled 668,064 tons in 1926. Ground gypsum and prepared wall plaster exported during the year totalled 10,062 tons, the United States, Newfoundland, Australia, and New Zealand being the chief importers of these materials. In 1926 the tonnage of magnesite produced in Canada decreased, but there was a considerable increase in value. The 1926 shipments were recorded as 4571 tons, compared with 5576 tons in 1925, and imports for the two years were 150 tons against 111 tons respectively, exports totalling 653 tons in 1926 and 834 tons in 1925. The International Magnesite Company and the Scottish Canadian Magnesite Company were the only producers of this material in Canada. Production of quartz in 1926 totalled 218,121 tons (197,224 tons in 1925), and imports of siliceous and crystallised quartz to a total of 2554 tons and of flint to the amount of 4731 tons were recorded during the same year. During 1926 Canada's salt output continued to increase, the high record of 233,746 tons in 1925 being surpassed by a production of 262,547 tons in 1926. Natural sodium sulphate shipped from Canadian deposits during 1926 amounted to 6775 tons, as compared with 3876 tons in the previous year.

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

In accordance with the provisions of By-Law 68, notice is hereby given that the Annual General Meeting of the Society of Chemical Industry will be held in the Debating Hall, University Union, Edinburgh, on Tuesday, July 5, 1927, at 10 a.m.

A detailed programme with form of application for tickets for the various functions has been issued to members.

In accordance with the provisions of By-Law 23, notice is hereby given that the following Members of Council retire from their respective offices at the forthcoming Annual General Meeting: -

Mr. Francis H. Carr, C.B.E., *President*; Dr. E. Frankland Armstrong, F.R.S., Prof. J. W. Hinchley, Prof. J. C. Philip, F.R.S., and Sir Richard Threlfall, K.B.E., F.R.S., *Vice-Presidents*; Mr. W. A. S. Calder, Mr. W. H. Coleman, Dr. William Cullen, and Mr. J. Arthur Reavell, *Ordinary Members*.

Mr. Francis H. Carr, C.B.E., has been nominated for re-election to the office of President under By-Law 19; Mr. E. V. Evans, Mr. C. S. Garland, Dr. H. Levinstein, and the Right Hon. Sir Alfred Mond, Bart., M.P., have been nominated Vice-Presidents under By-Law 20. Dr. E. W. Smith has been elected Honorary Treasurer, and Dr. E. Frankland Armstrong, F.R.S., has been elected Honorary Foreign Secretary.

Mr. A. J. Chapman, Dr. H. E. Cox, Dr. W. M. Cumming, Mr. George Gray, Mr. C. Norman Kemp, Prof. G. T. Morgan, F.R.S., Dr. F. L. Pyman, F.R.S., Mr. L. Guy Radcliffe, Prof. Joseph Reilly, and Mr. Harold Talbot have been nominated under By-Law 24 to fill four vacancies among the Ordinary Members of Council.

A Ballot List has been posted to every Member entitled to vote.

J. P. LONGSTAFF,
General Secretary

EXTENSION OF PERIOD FOR REDUCED RAILWAY FARES

Since the programme for the Annual Meeting was printed, the Railway Companies of Great Britain which agreed to issue tickets at the ordinary single fare and one third for the double journey to persons travelling to Edinburgh to attend the meeting have extended the validity of these tickets, and they will be **available from Saturday, July 2, to Monday, July 11**. These tickets will be obtainable at the time of booking on production of vouchers which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

It is urgently requested that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

PROPOSED EXCURSION TO ST. ANDREWS ON SATURDAY, JULY 9

The train will leave the Waverley Station, Edinburgh, at 9.30 a.m., arriving at St. Andrews at 11.22 a.m.

A visit to the University, including the Chemical Laboratories, will be arranged for the afternoon, and the St. Andrews University Court has kindly offered to entertain the members to tea in the University Buildings.

The return train will leave St. Andrews at 5.35 p.m., arriving in Edinburgh at 7.26 p.m.

Members will also have an opportunity of visiting other places of historic interest in St. Andrews or of playing golf.

AMERICAN SECTION

At the meeting held on May 6, the American Section passed the following resolution:—

Whereas Ira Remsen, a Past President of the Society and a leader in the development of chemical research in America, has been removed from us in the fullness of years by death, and *Whereas* the American Section of the Society desires to place on record its appreciation of his services to the science of chemistry, as a gifted teacher and as a director of research, *Therefore, be it resolved*, that the Section hereby recognises with sincere sorrow the loss which it has sustained in his demise, but at the same time rejoices in the fact that his genius and enthusiasm, which inspired so many of his students and fellow-workers during his life, will continue to bear fruit in the years to come, and will hold for him an honoured place in the history of chemistry throughout the centuries.

(Signed) JAMES KENDALL
CHARLES HERTY
HARLAN S. MINER

CALENDAR OF FORTHCOMING EVENTS

- June 9. OPTICAL SOCIETY. *Ordinary Meeting.* Imperial College of Science and Technology, Imperial Institute Road, South Kensington, S.W., at 7.30 p.m.
- June 14. RÖNTGEN SOCIETY. Tenth Sylvanus Thompson Memorial Lecture will be given in the Royal Society of Medicine, 1, Wimpole Street, W., at 8.30 p.m., on "The structure of the atom and radiation," by Sir J. J. Thomson.
- June 14 to 17. INSTITUTION OF ELECTRICAL ENGINEERS. Summer Meeting at North-Eastern Centre. Numerous visits to Works. Registration Office, The Central Station Hotel, Newcastle-upon-Tyne.
- June 15. ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY, Northampton Polytechnic Institute, St. John Street, Clerkenwell, London, E.C.1., at 8.15 p.m. "Electrorefining of silver," by E. Downs.
- June 15. SOCIETY OF GLASS TECHNOLOGY. Meeting at Sheffield.
- June 18. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. General Meeting, at 2.30 p.m.
- June 29. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2., at 4 p.m. Annual General Meeting.
- July 4 to 9. SOCIETY OF CHEMICAL INDUSTRY. Forty-sixth Annual Meeting in Edinburgh. (See CHEM. AND IND., May 20, 1927, p. 464.)
- July 4 to 8. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group.* Annual Meeting in Edinburgh. "Some aspects of the manufacture of fibrous cellulose," by Dr. J. L. A. Macdonald. A discussion will follow.

BRITISH ASSOCIATION OF CHEMISTS

The annual meeting of the London Section took place at the offices of the Association on May 20. In the absence of Mr. S. R. Price, M.B.E., Mr. E. R. Redgrove took the chair.

After the disposal of the formal business, Mr. Hy. T. F. Rhodes, General Secretary of the Association, opened the discussion upon registration. It was of great importance that interest should be aroused, and a strong opinion formed within the profession. No society, however great in numbers, or however perfect in organisation, could effect anything unless professional opinion as a whole demanded it. The Association had done a great deal in this connexion. Continuous propaganda had been carried out, not only in the chemical but in the public press. There was abundant evidence that public interest in this question was being aroused. Professional opinion was not yet united, and much friendly difference of opinion existed as to the ways and means of carrying the policy through. This, however, should encourage to greater effort, since there was little doubt that the whole profession was agreed upon all the fundamental issues.

Prof. G. T. Morgan, F.R.S., President of the Association, said it would be unwise to minimise the difficulties of the policy. At the same time, until the profession became in some sense closed the chemist could not hope for improved status. Chemistry has so enormously increased in scope that inadequate training was a much more serious question than it had been even a few years ago. Obviously registration would be a safeguard in this connexion. Again, a form of registration which was not able to adjust the supply of chemists to the demand would not be complete. He considered that an analogy between the profession of chemistry and those of medicine and law must not be pressed too far, since the functions of these professions and their relation to the community were different from that of chemistry. This, however, was not to say that registration for the profession of chemistry was impracticable. In order to succeed the chemist must develop his policy in a form which took into consideration the particular problems the profession had to face. But it was evident that a great deal had been done by the Association. The fact that the Association was as yet a young society, far from discouraging them, ought to encourage that energy, the complement of experience, which was the virtue of youth.

An interesting discussion followed, in which Mr. Macdonald, Mr. Gatehouse, Mr. Clark, and Dr. Atkinson joined. The question of the time limit allowed to those without academic qualifications was raised, the general secretary stating that the standing committee on registration was considering this question. In reply to questions by Mr. Macdonald and Mr. Clark, the General Secretary stated that at first registration would effect little more than giving the profession form and shape, but that that was a great deal. Educated men did not combine for the purpose of aggression, but in order the better to serve the community, and to win recognition by education of the public rather than by useless attempts at intimidation. The council had strictly kept this fact in mind in considering the Association's policy.

A resolution proposed by Mr. Dunford and seconded by Mr. Long, "That this meeting is in favour of the principle of registration, and prays the council to do all that is possible to give effect to the policy as soon as may be practicable," was carried unanimously.

A discussion followed upon the granting of certificates of membership. The meeting was of opinion that this was not desirable at present, and a resolution to that effect, proposed by Mr. Cosbie and seconded by Mr. Barrett, was passed.

Mr. C. B. Woodley, Secretary of the Association, gave an account of the position of the unemployment benefit fund and of the appointments bureau. An increasing number of employers approached the bureau direct. In connexion with salaries a large amount of work had been done. Many members had been advised as to the salary a particular position should carry, and in two cases through the Association's advice a member had obtained almost double the original salary offered.

CERAMIC SOCIETY

The Continental tour of the Ceramic Society was made the occasion of a joint meeting with the Czechoslovak Ceramic Society at Prague on May 6, when five papers were presented.

Dr. R. Barta, Secretary of the Czechoslovak Ceramic Society, reported on "The ceramic industry in Czechoslovakia." Czechoslovakia, next to England, is the richest country in Europe as regards ceramic raw materials, especially kaolin. There are also abundant supplies of clays, felspar, quartz, and refractory shales. The burnt clayware includes bricks, refractory products, pottery, stoneware, tiles, and porcelain. Other products include Portland and other cements, lime, magnesite, and glass. In Czechoslovakia are five Institutions where advanced instruction is given on ceramic subjects, in addition to a number of local centres where the instruction has a more limited range.

"Results of work carried out in the Silicate Research Department of the State Institute of Technology, Brno." Under this title is comprised four short papers contributed by Dr. O. Kallauner and colleagues. One relates to the determination of small amounts of magnesium in the presence of excess of ammonium salts, with special reference to the determination of magnesium in Portland cements. The second is concerned with the determination of soluble salts in clays and ceramic wares. The third paper discusses the injurious effect of nodules in brick products, and the fourth has for its subject a study of lead glycerine cements.

"The testing and behaviour of refractory material under stress at high temperatures," by Mr. A. J. Dale, B.Sc. In the ordinary refractory test an elongated tetrahedron or "cone" of the clay or brick to be tested is surrounded by standard "cones" which bend over or squat after definite heat treatments. The high temperature load test, as devised by Mellor and Moore, consisted in heating (in an electric furnace) small test pieces, subjected to definite pressure, until rapid collapse set in, the result being reported as the standard cone which collapsed in like manner. Evidence was found indicating that in certain cases failure in the test was due less to viscous squatting than to reduction in mechanical strength and

failure by shear. It also became clear that the temperature of complete collapse under load was often very indefinite. Hence further work was deemed necessary before rigid standardisation of the load test and the formulation of specifications based on the load test results. The author has been carrying out this work, which is still proceeding, and he describes the method of testing proposed as the result of these investigations, and gives the more important indications of the data collected during the past three years.

In the modified load test, the furnace adopted is essentially that designed and used by Mellor and Moore. The test piece rests on a column of specially made carborundum blocks, and pressure is applied by means of a thrust rod built up of similar carborundum blocks and cylinders. The fittings include an arrangement by which vertical movement of the test piece, thrust rod and supports, heated under any desired load, can be followed with a magnification of 10 to 40. A load test result can in this way be presented as a continuous curve, showing the progress of the subsidence and other characteristics of the test piece over a wide range of temperature. If desired, recording can be made autographic.

In order that expansion and subsidence data recorded may be comparable, standardisation of the size and shape of test pieces, as well as of the rate of heating, is necessary. The test pieces used are $3\frac{1}{2}$ in. \times 2 in. \times 2 in., with ends ground smooth and parallel. A rise of temperature of 50° C. per 5 min. is maintained throughout the test. The time factor being thus eliminated, the result can be recorded in actual temperatures.

Temperature readings are obtained by the use of a thermo-couple and an optical pyrometer. For the scale readings, a magnification of 16 is most generally suitable. Scale readings are taken every $2\frac{1}{2}$ or 5 mm., until very rapid or complete collapse of the test piece occurs. These readings are plotted against corresponding temperatures, and the resulting graph represents the behaviour of the tested material. The expansion readings include both test piece and carborundum expansions, but, as determinations on the thermal movements of carborundum material have produced only smooth and approximately linear expansion curves under high and low loadings and up to 1600 – 1700° C., any marked deviations from a smooth course in the modified load test result on a refractory product is characteristic of the test piece and not of the thrust rod or support material.

Silica products, with more than 92% silica, may contain a silicate glass, quartz, cristobalite, and tridymite in various proportions, and give different results accordingly with the modified Mellor and Moore test. Silica bricks containing unconverted quartz, when tested under a load of 4 lb. per sq. in., stood up until softening of the matrix caused squatting. Under a load of 75 lb. per sq. in., the same bricks began to fail at about 1500° C., and collapsed completely at 1570° C., owing to actual fracture. It is inferred that bricks containing unconverted quartz are liable to disruption under high external loadings at temperatures above 1250° or 1300° C., unless a specially elastic matrix is present. Silica bricks containing much cristobalite, under a load of 4 lb. per sq. in., stood up to the highest temperature attainable in the load test furnace without showing any abnormal

expansion at high temperatures. Under 50 lb. per sq. in. the brick failed at 1700–1730° C., and did not begin to deform appreciably until 1700° C. was reached. Such bricks should behave very well under industrial conditions of stress and high temperatures. Silica bricks with much tridymite showed under the 4 lb. per sq. in. load a subsidence range of 150° to 180° C., whereas with many silica products this range seldom exceeds 50° to 80° C. The temperature of collapse is very high, being over 1675° C., even under a load of 75 lb. per sq. in., and there is no rapid expansion at high temperatures nor marked rapid expansion at low temperatures. Such bricks seem specially suited for high temperature arch work.

The author suggests that the proper application of the modified Mellor and Moore load test will enable a scientific choice to be made of silica bricks for any specific type of industrial service.

With regard to fireclay products of ascertained composition, the results of ordinary refractory tests and porosity tests show that a brick with high ferric oxide content is not necessarily inferior in refractoriness at moderate temperatures, that a brick of low refractoriness may prove efficient enough below 1250° C., that high alumina content and moderate porosity favour refractoriness at temperatures up to about 1400° C., and that the temperature of complete squatting of a brick under load is not a safe guide as to behaviour of the material at lower temperatures.

Grog effects are briefly discussed, with special reference to the influence of the amount, the nature, and the grading of the grog.

Mr. W. J. Rees, B.Sc., contributed a paper entitled "Some notes on the use of Indian sillimanite." Bricks made from sillimanite with 10% ball clay bond were placed in a pot of molten lime-soda glass after a slight preliminary heating on the sill of the pot, and they did not crack or spall. These bricks were used to keep the pot-rim from floating too far to the left, and the founding temperature of the glass was 1350–1400° C. When removed from the pot after six weeks, the bricks were only slightly corroded—much less than fireclay bricks under similar circumstances. To get the best results from sillimanite bricks (or blocks) they must be burned at higher temperatures than those generally used for fireclay, the minimum being 1300° C. for sillimanite articles intended for contact with molten glass. It is advantageous to let the wet mixture of sillimanite and clay mature for 4 weeks or more before using. Much improved "bond" is obtained by maturing for 8 to 12 weeks—in the case of a mixture of 75 sillimanite with 25 ball clay. The pot dried much faster than an ordinary clay pot, and the total contraction from wet to dry was about 1 in 100. Though the pot costs about three times as much as one made from pot-clay, the longer life of such pots and the better quality of the glass much more than compensates for extra cost.

Sillimanite has been successfully used in the construction and repair of the sieges of pot furnaces, the mixture used being 75 sillimanite to 25 plastic fireclay. One such siege showed very little wear after three years in use. A sillimanite brick roof to a 3-ton Heroult electric furnace used for steel-melting at Sheffield lasted 132 heats, and the volume change of the bricks during use

was negligible. The normal life of a silica brick roof on this furnace is 60 heats.

Sillimanite bricks are giving very promising results in the arches and walls of high-pressure boiler furnaces with normal coal-firing and also with oil and pulverised-coal firing. Sillimanite shelves on the trucks of tunnel ovens are also giving good results. The mechanical strength at high temperatures of well burned sillimanite bricks with 15 to 25% of fireclay bond is much superior to that of fireclay bricks.

The results are given of tests for refractoriness (ordinary and under load), and of burning shrinkage, of sillimanite made up with various bonds.

The last paper, by Mr. A. T. Green, F.Inst.P., was on "The firing properties of refractory fireclay products." This paper was at once a general and a particular survey of the whole subject of fireclays and fireclay products in relation to the effects produced by heat. After a brief consideration of the constitution of fireclays, the nature of the firing operation was discussed, with particular references to the three outstanding periods, termed the water-smoking period (ranging normally up to about 250° C.), the oxidising period (500° C. to about 850° C.), and the vitrification range (from 800° C. to the finishing temperature). The water-smoking period is concerned with the expulsion (in a kiln or oven) of mechanical and hygroscopic water contained in the dried but unfired product, together with the colloidal water associated with halloysitic clays. The oxidation period is mainly concerned with the elimination of carbonaceous matter, the oxidation of iron compounds, and the decomposition of carbonates, sulphides, etc. During the vitrification range the fluxing action arising from the incipient fusion of the felspathic, micaceous, ferruginous, and other constituents of the original clay greatly affects the texture and strength of the product. The time-factors required to complete these operations vary with the nature of the clay, and with the design and manipulation of the kiln.

In the water-smoking period, too rapid expulsion of water may set up strains in the material, but experimental data relating to such strains are scanty. Reference is made to certain bricks, the water contents of which represent about 150,000, 108,500, and 66,800 c.c. of steam respectively, the largest of these volumes being practically 100 times the volume of the brick. Data obtained by Theobald and Green suggest that the time required for successful water-smoking is nearly proportional to the water-contents of the dried goods, i.e., in grogged fireclay bricks the water-content is the most important factor, outweighing all the others (texture, nature of clay, etc.). The controlling factors of water-smoking in industrial operations seem to be the moisture content of the original dried products, the rate of removal of water-vapour in the kiln, and the rate of rise of temperature.

In the oxidation period, many of the phenomena begin at about 500° C., as the burning out of carbonaceous matter from some fireclays, and the decomposition of ferrous carbonate. Iron sulphide in the presence of air begins to oxidise below 400° C., and at 1000° C. is fully converted into a mixture of magnetite and ferric oxide.

The formation of "black cores" is briefly alluded to, and the burning away of carbonaceous matter and the changes taking place in iron compounds are considered.

During the oxidation period the mechanical strength of the clayware is at a minimum, so that a general weakening of the finished product may result from additional thermal strains.

In the vitrification range, the heat-work produces vitrified or glassy material, which will surround the remaining particles and fill the interstices to an extent dependent on the properties desired in the finished product. The finer the grain, the greater the vitrification.

At about 800° C. fireclays begin to vitrify, the most fusible silicates beginning to melt or melting silicates being formed. Solution of other constituents gives rise to complications. The rate of vitrification of most fireclays is slow up to about 1200° C. With calcareous and very micaceous clays the range of temperature marked by involved chemical and physical actions is very small (perhaps not more than 50° C.), but with very good fireclays it may extend from 850° to 1450° C., with marked effects from 1250° C. upwards. As vitrification and its effects depend on the time-factor as well as on temperature, it is often beneficial in practice, after carefully heating up to the "maturing" temperature to "soak" for some hours to remove inadequate effects obtained in earlier stages.

It is inferred that crushing strength, apparent porosity, and sealed-pore value data when taken together give valuable indications of the vitrification of a fireclay product.

Loss of porosity is accompanied by a contraction of the clay mass as a whole. This volume-change, or, better, its rate of change, forms another criterion of vitrification.

The author proceeds to discuss the constitutional changes taking place during the vitrification range, and afterwards makes a brief reference to the colour changes in fireclays, due mainly to iron and calcium compounds.

Finally, in connexion with time-factors, some results are quoted concerning work done in an experimental kiln which indicate possibilities of some economy in the firing time of certain industrial kilns.

ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY

The 17th meeting was held at the Northampton Polytechnic Institute on May 18, when Mr. S. Wernick, B.Sc., read a paper on "The protective effect of metal deposits on iron." The Chair was occupied by Dr. W. H. Vernon. Mr. Wernick, opening his paper, said that the three important factors concerning electrodeposition for rust protection were the nature of the protective metal, the thickness and condition of the deposit and the conditions under which it had been deposited. So far as the first two points went, a useful guide was found in applying Nernst's solution pressure theory and the normal potentials of the metals commonly deposited. The same theory gave us a good picture of the mechanism of the rusting of iron, and this he outlined. It was thus seen theoretically that of the metals which had been deposited, only zinc, chromium and possibly cadmium could be expected, by acting anodically to the iron, to act as rust preventives. The conditions of deposition were, however, extremely important: such factors as the preliminary treatment, porosity of the base metal, structure of the deposit, type of solution used, throwing

power of the solution, mode of handling, and the final finish all entered into the production of an efficient deposit. The throwing power of a solution was particularly important in the case of articles with sharp bends or deep recesses. This fact, together with the fine structure obtainable from cyanide solutions, accounted for the marked superiority of these baths over acid sulphate solutions in the case for example of zinc.

Electrolytic zinc was superior to zinc deposited in any other way on account of its great purity. Nickel can act as an efficient protective provided its thickness is at least 0.001 in. Cobalt has given very good results with a copper underlay, and has stood up better than a copper-nickel deposit. Chromium was certainly comparable with zinc as a rust preventive. Chromium gave varying results mainly of a disappointing character—probably due to its proneness to passivity; a copper-nickel underlay gave improved results. In conclusion, he stressed the need for a standard corrosion test which should be laid down to render the results of different investigators comparable.

A communication was read from Mr. T. H. Turner, M.Sc., drawing attention to the unsatisfactory condition of modern commercial electroplate and the consequent increase in the specifications for "all-black" finishes. He heartily supported the suggestion for a standard corrosion test, which he proposed should be taken up in collaboration with the National Physical Laboratory and the British Engineering Standards Association.

Mr. E. A. Ollard said failure of electroplate was rather different from that of ordinary metal. He outlined three types of failure: (1) the plate itself gradually disappears; (2) pits form which open out, causing the rust to spread; (3) the plating breaks clear away. It would, therefore, be difficult to obtain corrosion data by weighing. With chromium, porosity resulted from strains in the deposit. An underlay of copper to nickel was not such good practice as a coat of nickel treated anodically then coppered and again nickeled. The adhesion of this combination was extremely good. Mr. W. James gave several practical instances of corrosion which had resulted from porosity, and said platers were frequently blamed for bad results which arose from the very poor material supplied. Mr. L. Wright, referring to the porosity of chromium plate, said he had found the chromic acid entered the deposit and was retained after the polishing process had "flowed" the surface—on removing this layer, the acid could be detected. In addition to the protection derived from the deposited metal, there was often an additional protection arising from the corrosion product formed.

Mr. S. Field said that heavy lacquers certainly increased the life of a deposit, but their object should be to get a plate which would not require a lacquer. A standardised salt spray is, perhaps, not the ideal corrosion test. Tests which were more in accord with atmospheric conditions, covering a longer period, will probably be used later. Mr. H. Perring suggested that a cyanide zinc coat followed by sulphate zinc to cover bends still rendered the latter the "weakest link in the chain." Mr. P. J. Craddock gave details of the "close plating" process, which was considerably thicker than electroplate and effectively closed up pores. It has been known to act as a protection for upwards of 20 years.

CORRESPONDENCE

IRISH CHEMISTS

SIR,—To add to a growing list of portraits of prominent Irish chemists, since the time of Sir Robert Boyle, and of chemists of other extraction who have worked in Ireland, the undersigned will be grateful for copies of pictures of Edmund Rolands (1819—1899), Robert Galloway (1822—1896), and William Plunkett (died 1884). The former two chemists were among Hofmann's first pupils in the Royal College of Chemistry, London. From 1849 to 1856 Rolands was Professor of Chemistry in Queen's College, Galway, and for part of this period he was Secretary of the Chemical Society, London, and edited the first two volumes of the Journal of that Society. Galloway was Professor of Applied Chemistry at the Museum of Irish Industry at Dublin (1857). When this institution became the Royal College of Science he held the Chairs of Chemistry and Metallurgy until he retired on pension in 1880. Plunkett was Assistant Professor with Galloway for many years, and published several papers on chemical subjects in the Proceedings of the Royal Irish Academy.

It may be of interest to mention that the portraits or pictures I have already collected under the above classification (excluding living chemists) are R. Boyle, F.R.S., P. Kirwan, F.R.S., W. Maple, J. Black, F.R.S., H. Davy, F.R.S., T. Hincks, R. Kane, F.R.S., J. Blyth, J. and E. K. Muspratt, J. Sheridan Muspratt, W. K. O'Sullivan, C. O'Sullivan, F.R.S., T. Andrews, F.R.S., E. Divers, F.R.S., J. Heron, J. Apjohn, F.R.S., J. Mallet, F.R.S., E. Reynolds, F.R.S., J. Bell, F.R.S., T. Rowney, Maxwell-Simpson, F.R.S., C. Cameron, W. N. Hartley, F.R.S., E. Letts, A. Senior, and Benjamin Moore, F.R.S.

There are at least two other Irish chemists of importance, namely, Brian Higgins and his nephew, William Higgins, F.R.S. In an early number of the *Dublin Quarterly Journal of Medicine*, W. K. Sullivan refers to a pencil sketch of these men by Cummerford, but so far I have not succeeded in tracing this or any portrait of the men.

Yours faithfully,
JOSEPH REILLY

Chemical Department,
University College, Cork

PERSONAL AND OTHER ITEMS

Sir Harry McGowan, President and Deputy-Chairman of Imperial Chemical Industries, Ltd., has been elected to a seat on the board of the Midland Bank, Ltd.

Prof. W. L. Bragg has been elected president of the Manchester Literary and Philosophical Society; Dr. H. Levinstein and Dr. R. S. Willows are elected as vice-presidents; and Mr. John Allan and Prof. E. A. Milne have been elected as secretaries.

Mr. H. J. Page, M.B.E., B.Sc., F.I.C., has resigned his position as Chief Chemist and Head of the Chemical Department at the Rothamsted Experimental Station on his appointment as Head of the Research Laboratories of Nitram, Ltd.

Major A. Rhydderch, B.Sc., has arrived in Australia, where he will join the staff of Hadfields (Australia), Ltd.

For some time Major Rhydderch was manager to Lake & Elliott, Ltd., of Braintree.

Mr. E. McKenzie Taylor has been appointed University Lecturer in agricultural chemistry, and Mr. W. A. Woodster has been appointed University Demonstrator in agricultural physiology and in mineralogy at Cambridge.

Dr. L. B. Mendel, professor of physiological chemistry at Yale University, has been awarded the annual medal of the American Institute of Chemists in recognition of his researches on food and nutrition. Dr. Mendel is the editor of the *Journal of Biological Chemistry* and a member of the editorial board of the publications of the American Chemical Society.

The late Mr. A. R. Musgrave, soap manufacturer, left £18,053.

The late Mr. Joseph Dixon, J.P., head of Peter Dixon & Sons, Ltd., paper manufacturers, left £377,366.

From Germany the deaths are announced of: Dr. M. Kempner, a well-known member of the Potash Syndicate; Dr. V. Rothmund, professor of physical chemistry in the German University of Prague; Prof. H. Noll, aged 70 years, well known for his work on the development of the chemistry of water supply; Prof. G. Tschermak, the well-known Viennese mineralogist.

Safety in Mines

The Safety in Mines Research Station at Harpur Hill, Buxton, is nearing completion, and will be formally opened in a week or so. The station has cost about £35,000 to complete, and will supersede the station at Eskmeals, Cumberland, which was too remote from mining centres. Equipment is provided for research on the explosibility of coal dust, on coal-mining explosives, on gob-fires, and other subjects, whilst laboratory work on these and related problems is carried out at Sheffield. Researches that require heavy and expensive plant are carried out in London at the Imperial College of Science and Technology.

Colonial Research Council

The Committee appointed by the Colonial Office Conference to make recommendations in regard to the establishment of a Colonial Scientific and Research Service, has been issued. It is proposed to set up a representative council to administer an Empire chain of agricultural research stations, to create a clearing house for information, and organise a "pool" of scientific workers. The annual cost of such a service is estimated at £175,000.

Smokeless Fuel

The directors of Low Temperature Carbonisation, Ltd., announce the successful completion and lighting up of the first of five batteries of retorts for the large-scale commercial production of "Coalite" smokeless fuel. When the remaining batteries are completed, there will be a plant of four batteries in day and night operation and one in reserve, with a throughput of 200 tons of coal per day. The estimated weekly output, based on the report of the Government Fuel Research Board issued in 1924 (since when the plant has been greatly improved and modernised) is:—"Coalite" smokeless fuel, 1020 tons; motor spirit, 1820 gals.; oils for lighting, burning,

lubricating, etc., 26,500 gals.; sulphate of ammonia, 20,000 lb.; and rich gas, 7,000,000 cb. ft.

Iron in Newfoundland

The iron mine at Snow's Pond, Conception Bay, Newfoundland, which has not been operated for several years, has been recently examined by experts, and it is understood that diamond drilling will be undertaken at once with a view to a further and more extensive development and operating at an early date. It is reported that the mine has been sold to Henry Ford, the motor-car manufacturer, Detroit, who will export the ore to the United States.

Steel Subsidy in S. Africa

A Bill has been introduced in the House of Assembly to promote the development of S. African iron and steel industries, under which a South African Iron and Steel Industrial Corporation will be formed with a capital of £3,500,000, and with a directorate of nine, five of whom would be Government nominees, for the acquisition of rights relating to the production or treatment of iron and steel, prospecting for deposits, and similar purposes. The Corporation's capital will consist of 2,000,000 ordinary £1 shares, of which the Government will take 500,000, the remainder being offered for public subscription. In addition, 1,500,000 £1 preference shares will also be offered for public subscription. An interesting provision of the Bill is that the requirements of the South African railways, in iron and steel, shall be bought from the Corporation at a price not more than 10% above the cost of the imported article. At present the Union Steel Corporation is the only company in the Union which is producing profitably, not only from scrap, but also from native ore.

German Exhibition of Chemical Apparatus and Plant

The fifth German exhibition of chemical apparatus and appliances will take place from June 7 to 19, at Essen, simultaneously with the conference of the "Verein Deutscher Chemiker" (Association of German Chemists). This is not the first occasion upon which the "Verein" has made public exhibits, as exhibitions have been held previously at Hanover, Stuttgart, Hamburg and Nuremberg under the name of "Achema." The name "Achema" is a combination of the initial letters of the "Ausstellung für chemisches Apparate-Wesen" (Exhibition of chemical apparatus, appliances, etc.). The important character of this trade exhibition, which is above all an exhibition for serious students of chemistry, is shown by the connexion which it has with the conference of the "Verein," which consists of four-fifths of the chemists in Germany, representing 10,000 members. Apart from the problems of chemical apparatus in general which arise from science and practice, apparatus for the chemical treatment of carbon will have special attention. The offices of the "Achema" are at Seelze (Hannover), to which all communications should be addressed.

Benzole Recovery in France

Recent decrees order the installation at the Grenoble, Mulhouse, and Bourbonnais gas-works of the Cie Genevoise de l'Industrie du Gaz and the Société les Compagnies réunies de Gaz et d'Electricité of plant to strip town gas completely of benzole. The work must be carried out within a period of two years.

REVIEWS

THE MICROBIOLOGY OF CELLULOSE, HEMICELLULOSES, PECTIN AND GUMS. By A. C. THAYSEN and H. J. BUNKER. Pp. viii + 363. London: Humphrey Milford, Oxford University Press, 1927. Price 25s. net.

The subject of the present volume has assumed considerable importance in recent years, both from the purely scientific and the industrial view-points. The authors have endeavoured to present, in a convenient form, an ordered survey of our present knowledge of the microbiology of polysaccharides, drawing freely on the mass of literature which has grown round their subject.

The book is divided into four sections, of which the first deals chiefly with the occurrence and properties of the various polysaccharides etc. under consideration. Whilst admitting the difficulties involved in an attempt to give a brief summary of the chemistry of these substances, the biochemist cannot but feel some slight disappointment on reading this section. Cellulose is summarily, but efficiently dealt with in some three or four pages, but in the case of pectin, hemicelluloses, etc., the more recent work has not been included, and some of the earlier work is misquoted (see especially pp. 11-12).

The second section deals with the classification and description of the various types of micro-organism associated with the decomposition of cellulose etc. This section gives a complete account of the occurrence and morphology of these organisms, contains a wealth of practical detail, and should be of considerable use to the worker in this field.

In the third section, the actual processes of decomposition effected by the organisms are described. The more recent work on the retting of flax is ably discussed; succeeding chapters are devoted to the microbiological decomposition of hemicelluloses and cellulose. The damage effected by micro-organisms to cellulose fibres and fabrics is a matter of grave economic concern; the chapter on this subject, and the ensuing one concerned with wood and wood pulp, is of great interest, and describes a field of research in which the authors have had much personal experience, as is evinced by considerable practical detail.

The book concludes with a short, perhaps too short, section on the industrial applications of microbiological reactions, including a very brief reference to the problem of the production of power alcohol.

Abundant references are given at the conclusion of each chapter. The format of the book is good; it is free from typographical errors, and the illustrations, mostly photomicrographs, are excellent. It should prove a very useful addition to the library of the biologist, bacteriologist and the biological chemist.

F. W. NORRIS

CHEMICAL ENGINEERING AND CHEMICAL CATALOGUE. Edited by Dr. D. M. NEWITT, A.I.Chem.E. Third edition. Pp. 404. London: Leonard Hill, 1927. Annual subscription, 10s. 6d.

Further improvement is to be remarked in the new, third edition of this useful catalogue, which appears to gain in scope every year, whilst losing nothing of its

lucidity. A foreword is contributed by Sir Robert Hadfield, then follow the separate catalogues of chemical products, and of plant and equipment. These sections consist of illustrated descriptions of the products of various firms in alphabetical order. Next come the classified index of chemicals and plant, a valuable list of trade marks and trade names, an index to industrial applications, a useful selection of technical and scientific tables and data, and a section giving a list of scientific and technical books.

The new matter consists of the list of trade names and the bibliography of technical books, whilst new tables and technical data have been added, the main index has been recast and enlarged, and the list of industrial applications has also been enlarged.

One regrets to note that the classified index has been moved from its former place at the beginning to a less convenient position. To demand absolute completeness in such a work would be unreasonable, but the classified index, already comprehensive in previous editions, has been considerably augmented, and has further gained in utility. Special commendation should be given to the list of industrial applications of various chemical products, and to the bibliography of technical books. The Catalogue can be safely recommended to all who are concerned with the sources and uses of chemical products and plant.

GMELIN'S HANDBUCH DER ANORGANISCHEN CHEMIE. Eighth completely new and revised edition. Edited by R. J. Meyer and Collaborators. System No. 5. Fluor. Pp. xvi+86. System No. 13. Bor. Pp. xix+142. Leipzig and Berlin: Verlag Chemie, G.m.b.H., 1926. Published by the Deutsche Chemische Gesellschaft. Price: (1) subscription, 11 m.; published, 18.50 m., post free. (2) Subscription, 17 m.; published, 22 m., post free.

Gmelin's Handbuch is so well known as a work of reference that it is needless to commend to chemists the parts now issued. They constitute a very complete and well-arranged account of the known chemistry of fluorine and boron, and will be of great service to all chemists whose work or interest lies in this field. It is, of course, impossible to test such works completely, but examining them by sampling, the writer has found that, with reference to those matters with the literature of which he is thoroughly familiar, the new Gmelin gives a complete and just account of the known facts. Hence, clearly, it may be inferred that, as a whole, these books are exhaustive and trustworthy.

One of the most striking impressions left by a perusal of these volumes is how scanty is our knowledge of the chemistry of fluorine. Of the 86 pages devoted thereto, about 25 are occupied by an exhaustive list of formulæ of complex fluorides, oxyfluorides, etc., with references; so that, apart from such compounds, a very full account of fluorine (18 pages, for example, being devoted to the preparation and properties of the element) occupies a surprisingly small space.

Chemists generally will welcome these volumes, and will feel themselves indebted to the authors for an extremely useful contribution to chemical literature.

H. V. A. BRISCOE

PARLIAMENTARY NEWS

British Industries Fair, 1928

Sir Burton Chadwick informed Mr. Hannon that the British Industries Fair would be held as usual next year in London and Birmingham, from February 20 to March 2. Forms of application for space in the respective sections will shortly be issued by the Department of Overseas Trade and the Birmingham Fair authorities, and preliminary arrangements had been made for publicity overseas. In view of the great success of the last Fair, a considerable increase in the number of exhibitors was expected, and arrangements were being made for the provision of a larger exhibiting area at both London and Birmingham.—May 23.

Chemistry and Physics (Courses for Lecturers)

In reply to Mr. Rennie Smith, Lord E. Percy said that from information in his possession he did not think that there was a demand among lecturers in technical institutions for short refresher courses of an advanced character in chemistry and physics. Lecturers in such institutions had ample opportunities, e.g., through membership of learned societies, of keeping in touch with scientific progress.—May 23.

Reparation Dyestuffs

Mr. McNeill informed Sir F. Wise that there have been no deliveries of reparation dyestuffs to this country during the year to March 31, 1927. The value of the deliveries of reparation dyestuffs to other Powers was 15,774,127 gold marks, or £773,243. — May 25.

COMPANY NEWS

BELL'S UNITED ASBESTOS CO., LTD.

At an extraordinary general meeting held on May 30, resolutions were passed to increase the capital of the company from £100,000 to £750,000 by the creation of 190,000 new preference shares of £1 each and 160,000 new ordinary shares of £1 each, and to alter the articles of association relating to the borrowing powers of the company. The funds thus raised will be used in connexion with the business of one of the associated companies—Bell's Poilite and Everite Co., Ltd., which, owing to an increasing turnover, requires additional working capital. Further funds are also required by the Poilite Co. to replace expenditure on buildings and plant—now practically completed—at the Harefield factory for the manufacture of poilite and rubber tiles. It is also expected that it will shortly be in a position to manufacture another new product, namely, asbestos-cement pipes for water mains etc., which possess advantages over cast iron and other pipes for similar purposes, the asbestos-cement pipes being free from the corrosive and vegetable growths so common in water mains. Arrangements have been made for Bell's United Asbestos Co. to acquire 100,000 preferred ordinary shares of £1 each in the Poilite Co., thus bringing its holding in this company up to £390,007, or over 76% of its total issued share capital, in addition to holding £125,500, or over 83% of the outstanding debentures.

BOOTS PURE DRUG CO., LTD.

Trading profits for the year to March, 1927, amounted to £789,570, compared with £850,228 for 1926, the net

profits amounting to £641,733, against £688,473. Preference dividends absorbed £96,750 (same), and £150,000 was again placed to reserve. After allocating £100,000 to a works development fund, and maintaining the dividend on the ordinary shares at 24%, the sum of £169,334 was carried forward, compared with £234,351 brought in.

BAKER PERKINS, LTD.

The net profit for 1926 was £63,722, compared with £61,965 for 1925. A final dividend has been recommended of 5%, making 9%, tax free.

BRITISH COTTON AND WOOL DYERS' ASSOCIATION, LTD.

The twenty-eighth ordinary general meeting was held on May 26, Mr. Adolph Hoegger (chairman) presiding. He expressed regret at the retirement, through ill-health, of Mr. C. R. Hindley from his position as a managing director since the inception of the Association and vice-chairman since 1909. Mr. C. R. Hindley will still retain his position as a director and vice-chairman. He also deeply regretted the deaths of Mr. T. B. Stewart the late manager of the Turnbulls, Ltd., branch, and of Dr. Adolph Liebmann, their consulting chemist. The net profits for the year to March 31, 1927, amounted to £81,805, compared with £142,349 in 1926. The sum of £25,000 was transferred to depreciation fund (now standing at £290,000); reserve received £20,000, and employees' benefit fund £5000. A dividend was declared of 5% on the ordinary shares, and £27,275 was carried forward. These results, though disappointing, were undeniable proof of the company's continued efforts in perfecting plant, processing methods, machinery, and the organisation generally. As a result of the coal-strike, an extra amount of £65,116 had been paid for fuel. The continual drop in processing prices had also to be taken into consideration. Referring to the company's interest in the Nuera Art-Silk Co., Ltd., the chairman said that Mr. F. J. Smith had been elected vice-chairman to the Nuera Co., and it was hoped that by such a close co-operation between the makers and the users of artificial silk, both companies would ultimately benefit materially. The dyestuffs industry in this country was now in a better position than it had been at any other time. During the past year many dyestuffs not hitherto made here had been produced by various British firms, most of these being "fast colours," including vat dyes, chrome mordant colours, and acid alizarine colours. There existed much uncertainty as to the term "fastness." A colour might be very fast to light, but not to washing or bleaching, or *vice versa*, and in order to deal with this question, a special Fastness Committee had been formed by the Society of Dyers and Colourists, in conjunction with British Textile Research Associations. The outstanding feature of the colour industry during the year was the formation of Imperial Chemical Industries, Ltd., of which the British Dyestuffs Corporation, Ltd., forms a part. Although British colour-users were still paying higher prices for dyestuffs than their foreign competitors, reductions in price were gradually and continually being made. With the recent consolidation of interests there seems every prospect of still further reductions, and of the British dyestuffs industry being placed on a solid foundation and becoming a real success.

PINCHIN, JOHNSON AND CO., LTD.

The usual dividend has been announced on the preference shares at 6½% per annum, less tax, for the six months to June 30, payable on July 1.

NATIONAL DRUG AND CHEMICAL CO., LTD.

The net profit for the year ending January 31, 1927 was £13,208, which, with income from investments in other companies, makes £23,030, which compares with a profit of £9069 for the previous year, and a loss of £6858 for the year 1924—25.

TURNER AND NEWALL, LTD.

This Rochdale firm of manufacturers of asbestos goods etc. has declared an interim dividend of 2½%, being the same as for the previous year.

ENGLISH CHINA CLAYS, LTD.

The eighth annual general meeting, held on April 26, was presided over by the chairman and managing director, Mr. R. Martin. The net profit for 1926 was £57,621, compared with £83,019 for 1925, and with £11,175 brought in, there was an available balance of £68,797. After payment of the preference dividends and an interim dividend of 2% on the ordinary shares, the sum of £22,084 remained, from which it is proposed to pay a final dividend of 1%, making 3%, on the ordinary shares, leaving £9395 to be carried forward. The general strike and the coal strike were the main causes of the decline in profits, the effect of which would still be felt in the early part of this year. Another cause was the failure of the negotiations for the formation of an association of china clay producers, followed by a further drop in the prices of the lower-grade clays. Satisfactory expansion had taken place in exports to America, India, Germany, the Netherlands, Belgium, Finland and Sweden, and the home market had absorbed more than could have been reasonably expected. Consumption in France, Italy and Spain showed a slight reduction. Improvements and extensions had been made at the various works of the company during the year, and soon practically the whole of the uneconomical plant would have been eliminated and the works equipped with up-to-date machinery. Since December, 1926, the company had acquired the whole of the shares of the North Goonbarrow China Clay Co., Ltd., and the directors were satisfied it would prove a great asset to the company. Mr. Hart Nicholls, sole managing director of the North Goonbarrow Co., had joined the board of the company. The chairman thought that 1927 would prove a more prosperous year than 1926. The import duty on translucent pottery should give a much-needed fillip to the home pottery trade.

NUERA ART-SILK CO., LTD.

The first ordinary general meeting was held on March 17, Sir James W. Paton, J.P., presiding. Reference was made to the loss to the company, through illness, of the services of Mr. H. O. Brandt, who was the first chairman. The company had purchased a site at Sutton Oak, near St. Helens, Lancashire, comprising about 20 acres, and including valuable water rights and reservoirs, for less than £20,000. Rapid progress was now being made in the erection of the factory, and temporary use had been made of some of the existing

buildings, in which the company had installed an experimental plant of considerable magnitude, which had been producing a very satisfactory silk and staple fibre on a semi-commercial scale during the last three months. A separate research department had been established, equipped with machinery and apparatus specially designed for the purpose of investigating and working out new processes. In this connexion, about a year ago, the company acquired an exclusive option on certain patents for the manufacture of new artificial silks and similar products, and these processes were now being investigated in co-operation with Messrs. Courtaulds, in this country, and the Vereinigte Glanzstoff Fabriken on the Continent. These processes were still in the experimental stage, but if they ultimately proved a commercial success, the company's share in the production of the new products would be very considerable. Dr. Herbert Levinstein and Mr. J. B. Walker were re-elected directors.

VISCOSE DEVELOPMENT CO., LTD.

The net profit for 1926 was £3478, making available, with £375 brought forward, £3852. A dividend has been declared of 3% (against 7½% for 1925). £1309 has been placed to reserve, and £144 carried forward.

CELANESE CORPORATION OF AMERICA

A dividend has been declared of 7% on the 7% cumulative first participating preferred stock, 3½% being on account of six months' arrears to June 30, 1925.

VEREINIGTE GLANZSTOFF GES.

The report for the past business year shows a net profit of 6,980,000 marks, as against 5,960,000 marks for the previous year. The total receipts amounted to 14,340,000 marks, or 1,680,000 marks more than in 1925, of which receipts from the manufacturers accounted for 12,190,000 marks. Expenses and taxation increased by 1,160,000 marks to 4,460,000 marks, 2,890,000 marks were applied to various settlements, and 147,238 marks were carried forward. A dividend has been paid of 15%. The report states that the situation improved during the second half of the year owing to the German price convention and international agreements, especially with the Italian firms. The Glanzstoff-Courtauld undertaking will begin production in the autumn, whilst the American Bemberg Corporation has already been working for several months, and the Aceta Company has already begun work. The patent for the "Airsilk" process, which was acquired last June by the Glanzstoff Company, has been handed over to the German Celta Company. Last year the company mainly developed the German and international participations, the total value of which now exceeds the value of the company's own plants. The participation account now amounts to 20,740,000 marks, having increased from 15,000,000 in 1925, the increase being mainly due to the purchase of shares of the Snia Viscosa, as well as the taking over of the Enka Company by the Glanzstoff Company. The report states that the works at present are fully occupied, and that the company anticipates good results in future, especially with regard to the co-operation with the foreign companies.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep. —6s. —6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor. 9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8½d.—9d. per lb. Crude 60's, 2s. 6d. 2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d. 1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 8d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 9d.—2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol.—1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/100, 1s. 2d.—1s. 11d. per gal. Solvent 95/100, 1s. 6d.—1s. 7d. per gal. Solvent 90/190, 1s. 3d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis. d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 3d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 4½d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum 1s. 3d. per oz.; 500 oz. lots.—1s. per oz.
 Acid, Boric B.P.—Cryst. £41 per ton. Powder £45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. p r lb.
 Acid, Citric.—1s. 6d.—1s. 7½d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 3½d.—1s. 5½d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzophenanthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.

Borax B.P.—Crystal £24 per ton, Powder £25 per ton, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 3d.—2s. 5d. per lb. Potassium.—1s. 1d.—2s. per lb. Sodium.—2s. 1d.—2s. 3d. per lb. All spot.

Calcium Lactate.—1s. 2½d.—1s. 4½d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Creosote Carbonate.—6s. per lb.

Ether moth.—1s. 1d.—1s. 1½d., per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiaac Carbonate.—6s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—22s. per cwt., 112 lb. lots.

Magnesium Carbonate.—Light Commercial £31 per ton net.

Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 10s. 6d.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonol.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—3s. per lb.

Phenazone.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar. 100s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 5d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Resorcin.—4s. per lb. spot.

Saccharin.—55s. per lb.

Salol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C.; 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 2d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonol.—7s. 6d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.

Thymol, Puriss.—10s. 3d.—12s. per lb., according to quantity.

Natural.—12s. 6d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (*ex Anethole*).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb.

Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb.

Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. 6d. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 9d. per lb.

Ethyl Cinnamate.—10s. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—32s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpineol.—1s. 6d. per lb. Vanilin.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—14s. 9d. per lb.

Camphor.—67s. 6d. per cwt. Cananga, Java, 20s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure.—6s. per lb.

Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 3d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 17s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 23rd. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C.2, on June 9th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Baillie and Todd. Heat insulation. 13,412. May 18.

Chem. Fabr. vorm. Schering. Manufacture of colourless melted products. 13,638. May 20. (Ger., 18.6.26.)

Dörstling. Roller mills. 13,363. May 18.

Filtrators, Ltd., and Saks. 13,385. See XXIII.

Fowler, and Fowler & Co. (Leeds), Ltd. Mixing-machines. 13,192. May 17.
 (Gordon. 13,269—70. See XXIII.)
 Harris. Filtration media. 13,288. May 17.
 Huhn. Drying or cooling material. 13,279. May 17.
 I.-G. Farbenind. Manufacture of emulsifying etc. agents. 13,273. May 17. (Ger., 19.5.26.)
 Menager. Manufacture of porous material. 13,585. May 20.
 Rein. Filtering systems. 13,168. May 17.

I.—Complete Specifications

5283 (1926). Ges. f. Linde's Eismaschinen. Separation of gases. (248,377.)
 12,303 (1926). Siemens Bros. & Co., Ltd., and Salmon. Optical pyrometers. (270,901.)
 3556 (1927). Goldman. Mixing and agitating machines. (267,480.)
 *28,069 (1926). Mase. Continuously determining a constituent of a mixture of gases. (271,027.)

II.—Applications

Battig. Production of hydrogen. 13,389. May 18. (Ger., 20.5.26.) Producing hydrogen in fractionation of furnace gases. 13,528. May 19. (Ger., 20.5.26.)
 Feige. Production and conversion of oils. 13,267. May 17. (Ger., 19.5.26.)
 I.-G. Farbenind. Production of liquid hydrocarbons etc. from natural ores etc. 13,508. May 19. Manufacture of valuable products from coal etc. 13,601. May 20. (Ger., 1.6.26.)
 Johnson (I.-G. Farbenind.). Splitting hydrocarbons. 13,101. May 10.
 Laing and Nielsen. Distillation of carbonaceous materials. 13,410. May 18.
 Sandiford. Composition fuel. 13,225. May 17.
 Sunderland. Artificial fuel. 13,305. May 18.

II.—Complete Specifications

28,548 (1925). Meyer. Fuels for internal-combustion engines. (270,772.)
 6231 (1926). Holmes & Co., Ltd., Parker, and Henshaw. Separation of tar and ammonia from fuel gases. (270,852.)
 6417 (1926). Litharge Recovery Corp. Separating metallic base reaction products from other derivatives in treatment of hydrocarbon oils. (263,730.)
 18,159 (1926). Debauche. Apparatus for drying and distilling lignite, peat, etc. (270,921.)
 20,942 (1926). La Riboisiere. Motor fuels. (257,613.)
 23,930 (1926). Bowater. Manufacture of water-gas. (270,948.)
 30,214 (1926). Debauche. Transforming lignite etc. into fuel of high calorific value. (270,976.)
 444 (1927). International Combustion Engineering Corp. Treatment of coal. (264,160.)
 6419 (1927). Deutsche Erdöl-A.-G., and Bomecke. Gas-purifying apparatus. (271,018.)
 *6878 (1927). A.-G. f. Chem. Ind. Converting high-boiling hydrocarbons into low-boiling hydrocarbons. (271,042.)

III.—Application

Still. Recovering sulphuric acid from acid-tar of benzol purification. 13,122. May 16. (Ger., 20.9.26.)

III.—Complete Specification

6231 (1926). Holmes & Co., Ltd., Parker, and Henshaw. See II.

IV.—Applications

British Dyestuffs Corp., and Wellacott. Dyestuffs for dyeing cellulose ethers etc. 13,401. May 18.
 I.-G. Farbenind. Production of anthraquinone derivatives. 13,509. May 19. (Ger., 8.6.26.)
 Johnson (I.-G. Farbenind.). Manufacture of complex metallic compounds of α -hydroxyazo dyestuffs. 13,602. May 20.

IV.—Complete Specifications

30,908 (1925). Badische Anilin & Soda Fabr. Manufacture of anthraquinone derivatives. (244,462.)
 789 (1926). British Dyestuffs Corp., Shepherdson, Tatum, and Bunbury. Manufacture of anthraquinone intermediates. (270,778.)
 790 (1926). British Dyestuffs Corp., and Tatum. Manufacture of anthraquinone intermediates. (270,779.)
 5421 (1926). Imray (I.-G. Farbenind.). Manufacture of anthraquinone derivatives. (270,840.)
 10,781 (1926). I.-G. Farbenind. Manufacture of water-soluble condensation products. (251,294.)
 20,688 (1926). British Dyestuffs Corp., Rodd, and Everatt. See XX.
 22,146 (1926). Soc. Chem. Ind. in Basle. Manufacture and application of dyestuffs. (258,854.)
 9388 (1927). British Dyestuffs Corp., Shepherdson, Tatum, and Bunbury. Manufacture of anthraquinone intermediates. (271,023.)
 *12,068 (1927). I.-G. Farbenind. See VI.

V.—Applications

Carpmael (I.-G. Farbenind.). Protecting wool etc. against insects. 13,374. May 18.
 Craven, and Yorks Dyeware & Chem. Co. Treatment of wool. 13,402. May 18.
 Kantawala. Manufacture of wool substitutes. 13,084. May 16.

V.—Complete Specification

*26,772 (1926). Böhm. Preparation of animal hair for felting. (271,026.)

VI.—Applications

British Dyestuffs Corp., and Wellacott. 13,401. See IV.
 Heberlein & Co. Producing pattern effects on textiles. 13,123. May 16. (Ger., 25.5.26.)

VI.—Complete Specifications

10,095 (1926). British Dyestuffs Corp., Baddiley, Chorley, and Brightman. Dyeing artificial silk. (270,883.)
 22,146 (1926). Soc. Chem. Ind. in Basle. See IV.
 *12,668 (1927). I.-G. Farbenind. Production of azo-dyestuffs on weighted silk. (271,089.)

VII.—Applications

Battig. 13,389 and 13,528. See II.
 Carpmael (I.-G. Farbenind.). Absorbing ammonia etc. from gases. 13,272. May 17.
 Castner-Kellner Alkali Co., Ltd., Moore, and Polack. Manufacture of ammonium chloride. 13,318—9. May 18.
 Haddan (Stackable). Manufacture of dicalcium phosphate etc. 13,488. May 19.
 Müller. Production of synthetic ammonia. 13,388. May 18. (Ger., 19.5.26.)
 Still. 13,122. See III.
 Synthetic Ammonia & Nitrates, Ltd., and Ewan. Production of hydrocyanic acid from formamide. 13,650. May 21.
 Weitz. Separation of alkali salts. 13,626. May 20. (Ger., 26.5.26.)

VII.—Complete Specifications

31,321 (1925). Petersen. Manufacturing sulphuric acid. (244,764.)
 4448 (1926). Marks (Parker Rust Proof Co.). Production of high-acid phosphates. (270,820.)
 4600 (1926). Packards & J. Fison (Thetford), Ltd., and Maudsley. Sulphuric acid chambers. (270,826.)
 6231 (1926). Holmes & Co., Ltd., Parker, and Henshaw. See II.
 31,880—1 (1926). Petersen. Manufacture of sulphuric acid. (270,988—9.)
 5019 (1926). Johnson (I.-G. Farbenind.). Manufacture of hydrated chromic chloride. (271,016.)

*12,656 (1927). Titan Co. Akt. Manufacture of titanium compounds. (271,085.)

VIII.—Applications

British Thomson-Houston Co., Ltd. Tinting glass. 13,372. May 18. (U.S., 18.5.26.) Heat-resistant compounds. 13,596. May 20. (U.S., 20.5.26.)

Menager. 13,585. See I.

Migeot Frères et Arnould. Enamels. 13,492. May 19. (Fr., 26.6.26.)

Pittsburgh Plate Glass Co. Leers. 13,380. May 18. (U.S., 29.7.26.)

Vitreux Co. Clay products etc. 13,149. May 16. (U.S., 22.6.26.)

IX. Application

Verein. Stahlwerke A.-G. Building material. 13,237. May 17. (Ger., 22.5.26.)

IX. Complete Specifications

30,882 (1926). I.-G. Farbenind. Production of cements. (263,124.)

3906 (1927). Chassevent. Tempering plaster. (266,335.)

*12,949 (1927). Harnisch. Manufacture of artificial stone. (271,108.)

X. Applications

Carlisle and Silva. Production of steel etc. from titaniferous ores etc. 13,411. May 18.

Farrbrother (Remfry & Son). Granulating etc. aluminium. 13,130. May 16.

Jackson (Siemens & Halske A.-G.). Treatment of metals. 13,710. May 21.

Morris Motors (1926). Ltd., and Smart. Case-hardening etc. iron etc. 13,713. May 21.

Smith. Treatment of ores containing platinum. 13,719. May 21.

Soc. Ital. di Elettrochimica, and Verney. Production of aluminium in electric furnaces. 13,500. May 19.

X. Complete Specifications

28,593 (1925). Lacour and Lindh. Tough annealing of metal alloys. (243,006.)

3867 (1926). Michel. Protection of molten baths of easily oxidisable metals. (257,221.)

4525 (1926). Fairweather (Etabl. Métallurgiques de la Gironde). Light aluminium alloys. (270,824.)

8264 (1926). Cornelius. Producing dense iron and iron alloys directly from oxide ores. (252,077.)

30,976 (1926). Limbourg. Substitute for platinum. (270,974.)

*12,662 (1927). Bührmann. Superheating blast-furnace and cupola-furnace slag. (271,087.)

*12,665 (1927). Michel. Metallurgy of readily oxidisable metals such as magnesium. (271,088.)

XI.—Applications

Bedford. Electric accumulators. 13,570. May 20.

Codd. Galvanic batteries. 13,375. May 18.

Comp. Franç. pour l'Exploit. des Proc. Thomson Houston. Electric dry cells etc. 13,544. May 19. (Fr., 19.5.26.)

Electric Furnace Co. (Northrup). Electric furnaces. 13,708. May 21.

Soc. Ital. di Elettrochimica, and Verney. 13,500. See X.

XI.—Complete Specifications

11,081 (1926). Lahousse. Electric insulating material. (251,970.)

27,829 (1926). I.-G. Farbenind. Mounting electrodes of closed electric furnaces. (263,756.)

*7311 (1927). Pechkranz. Electrolyser diaphragms of the filter-press type. (271,043.)

*12,932 (1927). Siemens & Halske A.-G. Electromagnetic bodies. (271,106.)

XII.—Application

I.-G. Farbenind. Soap preparations etc. 13,099. May 16.

XII.—Complete Specification

*12,295 (1927). I.-G. Farbenind. Manufacture of soap-like preparations. (271,071.)

XIII.—Complete Specifications

4553 (1926). Bakelite Ges. Purification of condensation products from phenols and aldehydes. (248,726.)

21,872 (1926). Marconi's Wireless Telegraph Co. Writing-fluids. (257,954.)

*2594 (1927). Kunstharzfabr. Pollak. Manufacture of artificial compositions. (271,037.)

XIV.—Application

I.-G. Farbenind. Preserving rubber latex. 13,366. May 18. (Ger., 28.5.26.)

XIV.—Complete Specification

5196 (1926). Anode Rubber Co., Ltd. Production of homogeneous rubber deposits from rubber latex. (257,885.)

XV.—Application

Herold A.-G., and Jaeger. Manufacture of white artificial horn. 13,260. May 17.

XVI.—Applications

I.-G. Farbenind. Fungicide. 13,370. May 18. (Ger., 18.5.26.) Production of fertilisers. 13,700. May 21.

Read. Production of fertilisers. 13,649. May 21.

XVI.—Complete Specification

25,871 (1926). Cerasoli. Fertilisers. (270,957.)

XVII.—Complete Specifications

4474 (1926). Ackers. Manufacture of icing sugar. (270,822.)

*12,183 (1927). Treuhand-Ges. Bartmann & Co. Treatment of materials containing starch. (271,068.)

XVIII.—Complete Specifications

28,318 (1925). Jansen. Fermentation of sugar and production of yeast. (270,770.)

5393 (1926). Commercial Solvents Corp. Fermentation processes for the production of butyl alcohol and acetone. (249,833.)

XIX.—Applications

Brighthouse. Concentrating fish. 13,051. May 16.

Miles and Reilly. Preparation of vegetable food. 13,141. May 16.

Stejskal. Preparation of a nutrient medium. 13,264. May 17. (Austria, 17.5.26.)

Zierer. Preparation of a mild aromatic yoghurt-curdled milk. 13,504. May 19. (Austria, 9.6.26.)

XIX.—Complete Specifications

804 (1926). Loon. Treating meal, flour, etc. with per-compounds. (245,801.)

*13,264 (1927). Stejskal. Preparation of a nutrient medium. (271,120.)

XX.—Applications

Arnold (Standard Development Co.). Manufacture of metallo-organic compounds. 13,723. May 21.

Chem. Fabr. vorm. Schering. Obtaining germ gland hormones. 13,531. May 19. (Ger., 20.5.26.)

Erslev. Preparing aqueous solutions of benzoic acid. 13,423. May 19.

I.-G. Farbenind. Manufacture of acid derivatives of the $\alpha\alpha'$ -dimethyl- γ -hydroxypiperidine- β -carboxylic acid esters. 13,124. May 16. (Ger., 17.5.26.)

XX.—Complete Specifications

917 (1926). Buchner. Cyclic process of producing soluble salts of organic compounds of an acid character. (246,142.)

4194 (1926). British Celanese, Ltd., and Skertchly. Purification of acetic anhydride. (270,809.)

5393 (1926). Commercial Solvents Corp. See XVIII.

16,840 (1926). Carbide & Carbon Chemicals Cor
Manufacture of glycols. (264,124.)

20,688 (1926). British Dyestuffs Corp., Rodd, and Everatt.
Separation of tertiary from secondary and primary amines.
(270,930.)

29,842 (1926). I.-G. Farbenind. Catalytic dehydrogena-
tions. (262,120.)

*7541 (1927). Holzverkohlungs-Industrie A.-G. (Concen-
trating volatile aliphatic acids. (271,044.)

*12,907 (1927). Consort. f. Elektrochem. Ind. Manu-
facture of butyric aldehyde. (271,103.)

XXI.—Applications.

Bernet. Producing light-sensitive films. 13,631. May
20. (Switz., 21.5.26.)

Berthon. Reproducing photographic prints. 13,632. May
20. (Fr., 1.6.26.)

I.-G. Farbenind. Photographic emulsions. 13,274. May
17. (Ger., 20.5.26.)

XXI.—Complete Specifications

5372 (1927). I.-G. Farbenind. Photographic silver halide
emulsions. (271,039.)

*12,935 (1927). Chem. Fabr. (vorm. Schering.). Photo-
graphic gelatin papers. (271,107.)

XXIII.—Applications

Filtrators, Ltd., and Saks. Treatment of feed water.
13,385. May 18.

Gordon. Process for conditioning etc. water. 13,269 - 70.
May 17.

XXIII.—Complete Specification

*12,542 (1927). Bourgognion and Philips. Treatment of
water. (271,079.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and
Intelligence), 35, Old Queen Street, London, S.W., has
received the following inquiries for British goods. British
firms may obtain further information by applying to
the Department and stating the specific reference
number: *Argentina*: Glassware, articles for domestic
cleaning and polishing (551). *Australia*: Perfumes, soaps
(517); Hollowware, glassware (520); Instrument
equipment for boiler house and turbine room (B.X. 3531).
Austria: Iron ore, smelted aluminium and nickel
(528). *British India*: Pig-iron, creosote, paper (Director-
General, India Store Department, Branch No. 10,
Belvedere Road, Lambeth, S.E.1). *Czechoslovakia*: Tin,
lead, antimony, phosphor copper (A.X. 4734). *Dominican
Republic*: Galvanised iron sheets, chinaware, lard, soya
bean oil (552). *Egypt*: Iron and steel, metals (A.X. 4723).
Germany: Dyes, paint, varnish, chemical products
(530). *Holland*: Chemicals (acids, dyes, sulphate of
ammonia, etc.) (532). *Italy*: Non-ferrous metals and
ferro alloys (536). *New Zealand*: Aluminium hollow-
ware (526); electric insulators (B.X. 3533). *Norway*:
Gum arabic, sole crepe rubber (541). *Rumania*: Palm
oil, tallow (542). *Uruguay*: High-tension cables
(B.X. 3539).

British Industries Fair

Larger exhibition areas in both London and Birming-
ham are to be provided for next year's British Industries
Fair, according to an answer given recently in the
House of Commons (on Monday, May 23) by the Parlia-
mentary Secretary to the Board of Trade (Sir Burton
Chadwick, M.P.). The Fair, it was stated, would be

held from February 20 to March 2. Forms of application
for space in the respective sections would shortly be
issued by the Department of Overseas Trade and the
Birmingham Fair authorities, and preliminary arrange-
ments had been made for publicity overseas. In view
of the great success of the last Fair, a considerable
increase in the number of exhibitors is expected by the
Board of Trade.

Imported Petroleum

The Board of Trade has exempted petroleum and its
liquid products from the requirement that imported
goods bearing a British name or trade mark must be
accompanied by an indication of origin.

Safeguarding of Industries Act

Cadmium mass (consisting substantially of finely-
divided metallic cadmium and iron partially oxidised)
has been exempted from the duty imposed by Part 1
of the Safeguarding of Industries Act in respect of its
content of cadmium hydroxide.

The British Chemical and Dyestuffs Traders' Associa-
tion, Ltd., have been advised by the Board of Trade
that the Board do not propose to recommend H.M.
Treasury to issue Exemption Orders in respect of
cocaine and cocaine hydrochloride, as they understand a
home-maker is preparing to manufacture these products.
Further, the Board report that the application in respect
of hydroquinone is still under consideration

New Dyestuffs

The British Dyestuffs Corporation, Ltd., has issued
a pattern card illustrating Duranthrene Brilliant Violet
2B Paste. This new vat colour is of special interest
to the dyer of wearing and washing materials, embroi-
dery yarns, etc., because of its shade, excellent fastness
to light, and very good fastness to washing, hot pressing,
and water spotting. It is also used for calico printing,
the prints obtained giving good fastness to washing.

News from Advertisements

The Newcastle and Gateshead Gas Company invite
applications for the position of chief chemist (p. viii).

A technical and analytical chemist, with 20 years
wide industrial experience, wishes partnership in con-
sulting practice at home or abroad (p. viii).

The College of Technology, Manchester, invites appli-
cations for its prospectus, giving particulars of Degree
Courses in Technology (p. viii).

EDITORIAL

Synthetic Aliphatic Chemicals

COMING events are said to cast their shadows before them, but occasionally, in the reported developments in commercial enterprises, we have detected more shadow than substance. This cannot be said, however, of the manufacture of ethylene glycol, ethylene dichloride, isopropyl alcohol and other higher aliphatic alcohols, the production of which has revealed a new and important branch of applied chemical endeavour. From many angles during the past few years we have been watching with interest the progress of research in the field of synthetic aliphatic chemicals, and there would appear to be no doubt now that production upon a large commercial scale has arrived. We are prompted to mention the subject more especially for two reasons. First, as noted in our columns recently, the Board of Trade has given notice that representations have been made under Section 10 (5) of the Finance Act, 1926, regarding the removal of ethylene glycol from the Schedule to Part I of the Safeguarding of Industries Act. Secondly, we recently received and published in our issue of May 20 an illuminating letter from Dr. Weidlem, Director of the Mellon Institute of Industrial Research, U.S.A., dealing with the present position of ethylene glycol.

There can be no doubt that ethylene glycol is being produced to-day in very large quantities—we have seen estimates of its annual production varying from ten to a hundred million pounds, and, at a price of about £110 per ton, it is approaching the battleground of competition with glycerin. Glycol dinitrate is a valuable material for explosives manufacture, and it possesses an important property not common to nitro explosives such as nitroglycerin, in that it confers non-freezing qualities upon the products with which it is incorporated. Glycol effectively replaces glycerin in anti-freeze solutions for the cooling systems of motor-car engines, and extended investigations into its physiological properties have shown that it may replace glycerin in many toilet preparations—materials which provide no incon-

siderable outlet for glycerin supplies. Further, the ethers of ethylene glycol have recently been shown to possess novel characteristics in regard to their use in compounded pyroxylin lacquer solvents, and the potential demand for glycol in this direction is very large.

In many of its uses, then, ethylene glycol appears as a competitor of glycerin, and British producers and exporters of glycerin will be carefully assessing the minimum cost of its production. That this can be brought below £140 per ton, and perhaps as low as the present price of glycerin, seems to be very possible. Ethylene, from which the glycol is made, is obtainable in enormous amounts at a very low cost from the huge resources of natural gas and petroleum cracking still gases available in the United States. By combination with hypochlorous acid, made by a continuous process from water and very low-priced chlorine, ethylene chlorhydrin is made and converted with reasonable ease into the glycol. The rapid progress of the manufacture of glycol and the equally rapid fall in the market price of the product leave little room for doubt that glycerin makers will shortly have a formidable competitor in the field. Glycerin is, however, a by-product of soap manufacture, and its price on the market can undoubtedly be considerably reduced in case of need. A parallel set of circumstances arose when synthetic acetic acid came strongly into the market a few years ago, for wood distillers reduced the price of acetate of lime, and hence of acetic acid, at the expense of methyl alcohol, which at that time was not being made synthetically. The situation in the glycerin market will soon be an interesting one.

Ethylene glycol is not the only important example of synthetic aliphatic chemicals which have recently come to the fore. Leaving out of consideration synthetic methyl alcohol—soon, we hope, to be a British product—there are ethylene dichloride, isopropyl alcohol, still higher homologues of ethyl alcohol and amyl acetate, to mention a few. Here, again, America holds a commanding position by reason of her supplies of natural gas, ethylene, propylene and pentane. From the last-

named, existing in natural gas gasoline, amyl chloride is made and readily transformed into amyl acetate, and so a valuable solvent is produced very cheaply. Similarly, ethylene dichloride is simply made from ethylene, and large amounts are coming on to the market. The first commercial quantities were offered in 1923 at about 1s. 6d. per lb. In 1924 the price was reduced to 1s. per lb., and in 1926 to 5d. To-day, ethylene dichloride can be bought in America in tank car quantities at the amazingly low figure of 3d. per lb. The significance of this fact becomes apparent when we remember that, in addition to its use as a solvent, ethylene dichloride may be made the starting material for the comparatively simple manufacture of such substances as glycol diacetate, ethylene diamine, dibenzyl (made from ethylene dichloride and benzene), benzaldehyde and benzoic acid (from dibenzyl), succinic acid, and so on, whilst many others will suggest themselves to the acute chemical technician.

In this country we are not blessed with immense supplies of natural hydrocarbon gases such as have made possible the production of natural gas carbon or gas black and the aliphatic chemicals noted above as an important American industry, but it is not impossible that other raw materials will be found by British manufacturing chemists. By suitably cracking hydrocarbon oils a gas can be made which contains 50% of ethylene hydrocarbons associated with paraffins and other bodies. Certain oil gases contain ethylene and propylene in approximately equal proportions, and by continuous fractional combination with chlorine or sulphuric acid the chlorhydrins or sulphuric acid esters of corresponding alcohols can be made. In this way we have possible sources of the glycols and alcohols made from very cheap starting material. Much work has already been accomplished, both in the laboratory and the works, upon the technique of the absorption of ethylene and propylene in sulphuric acid, and ethyl alcohol has been made on a works scale—but not at an economic price—from the ethylene existing in coke-oven gas. The commercial development of such a process and similar chlorination processes may only await the advent of cheaper and more abundant starting materials, and cheap oil gas of a suitable composition may provide this. Finally, we may note with satisfaction that solvent alcohols such as isopropyl alcohol and butyl alcohol are already being produced in comparatively large amounts in this country, the first by the hydrogenation of acetone and the second by fermentation processes from the starch of cereals. The world has long known the production of synthetic aromatic chemicals from coal tar. The manufacture of equally important synthetic aliphatic chemicals has already commenced in earnest, and who shall define the limits of its expansion?

The Oil, Colour and Chemical Exhibition

We are fortunate in that we are not old enough to possess personal memories of the days when Hyde Park was converted into the gigantic glasshouse which has taken permanent root in Sydenham. The Prince Consort on his monument remains as a token of those serious Victorian days, when science first became worthy to be

mentioned in polite company, and the distinguished band of 1851 exhibitors provides a tribute to the foresight of those who organised the first great Exhibition. It would be rather a serious disqualification for anyone who had to write about exhibitions but did not remember the Great Exhibition had there not been Wembley, that unequalled picture of the industries and resources of the Empire. We were fortunate in that we did see a great deal of Wembley, though, like everyone else, we were physically unable to see all we would have liked to see. After Wembley there came an impetus towards the provision of specialised exhibitions, and we had the excellent exhibition of chemical plant, arranged by the British Chemical Plant Manufacturers' Association, which was so conspicuous a feature at the last annual meeting of the Society of Chemical Industry; and, of course, we have also each year the splendid Chemical Section of the British Industries Fair, organised by the Association of British Chemical Manufacturers. Now we have another type of exhibition, in which the makers of plant and products have been drawn together, so as to present a picture of the activities of several related industries. This exhibition—the International Oil, Chemical and Colour Trades Exhibition—opens on June 11, and remains in activity during the following week. Judging from the account of the exhibition which we publish this week in a special supplement, there will be no lack of interest to the visitor, be he of commercially or merely of scientific bent. Various firms are showing ingenious devices which fill containers of various kinds with liquids or solids. Weighing machines will be on view which are so conscientious in the performance of their duties that they refuse to work if the operator does not perform one very simple movement correctly. There are mills of every kind, size and form, and the expert will be able to judge how truly cylindrical cylindrical rollers can be made, and discuss the merits of methods of adjusting rolls that work to limits which one associates rather with the microscope. Advocates of the finest grinding will have weary limbs before they have studied all of the many types of machinery devised to grind and dress the most varied substances. Blending is an operation which is equally cared for—one machine is able to blend an ounce of one material perfectly with a hundredweight of another—and there are machines which separate impurities with accuracy and economy. In addition to actual machines, there will be many working models, amongst which we note the interesting Raymond mill. Fullers' earth makes an interesting exhibit, and we shall look forward to an inspection of the many grades which are prepared from material mined in Surrey and Somerset, remembering a visit to a Pompeian "fullonica," excavated from the debris flung by stormy Vesuvius. The exhibit of filter papers reminds one that they have many important industrial uses, apart from forming a medium for calculations in the laboratory. Paints there will be in all their splendour, with enamels, lacquers and, of course, a variety of pigments, solvents, resins, and so on. Prime movers, such as fuel oil engines, will be displayed, and many other interesting exhibits will claim attention.

THE CHARACTERISTICS AND PROPERTIES OF THE MAIN TYPES OF ASBESTOS FIBRES

By J. N. LONGLEY

The name "asbestos" is applied indiscriminately in industry to several classes of fibrous minerals which fall into two main groups:—

1. Serpentine group, of which the principal member is chrysotile, the silky white fibre of commerce.
2. Amphibole group, which includes crocidolite (South African Blue), amosite, tremolite, actinolite, etc.

Of all the minerals comprising these main groups, only two find any important application in modern engineering problems. These, in order of importance, wide distribution and usage are—1. Chrysotile (white); 2. Crocidolite (blue).

The last two members of the amphibole group have attracted a little interest, and are, therefore, also described briefly, as a third, but much less important family, named "Hornblende."

CHRYSOTILE (WHITE)

This family is the one of greatest manufacturing interest, and 90% of the asbestos used in industry belongs to it. It occurs in veins or striations in the mother rock, "serpentine," and is very widely distributed, though quarried mostly in Canada and Rhodesia. The fibres are arranged perpendicularly to the wall of the vein, and are separated in compact masses from the adherent matrix of serpentine by crushing. These masses are resolved, by further crushing, into fibres, elongated crystals, the length of which is as the whole depth of the vein of which they were part. The diameter of each separated fibre appears to be fairly constant at about 1,500,000 in., i.e., about 1/100th of the diameter of the cotton fibre. They are white, silky, and very flexible, and their length may be as low as $\frac{1}{8}$ in., and as high as 5 or 6 in. Under a magnification of 1000 diameters, the fibres appear to be quite smooth, and square in section. The specific gravity of the family ranges from 2.25 to 2.27.

In general, chrysotile is a hydrated magnesium silicate, of the form $3\text{MgO} \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$, but it is seldom free from impurity. Other metals appear to replace partly the magnesium, to form uniform complex hydrated metallic silicates; these other metals are generally aluminium, iron, calcium, sodium and potassium, and their total amount varies but little. Typical analyses are shown in Table 1.

TABLE 1
Analyses of Chrysotile (White) from Various Sources

Type	High Grade Canadian %	Medium Grade Canadian %	Rhodesian Low Grade %	Rhodesian Medium Grade %	Rhodesian High Grade %
Carbonic Anhydride	—	—	3.0	1.81	0.35
Combined Water	15.2	13.15	10.55	11.43	14.42

Calcium Oxide	0.51	0.83	0.96	—	—
Magnesium Oxide	42.57	33.38	34.04	38.02	41.77
Sulphuric Anhydride	0.10	0.08	trace	—	trace
Alkali and loss	0.23	0.50	0.15	—	0.20

CROCIDOLITE ("SOUTH AFRICAN BLUE")

This type, lavender blue in colour, occurs in banded gneiss in a manner similar to that in which chrysotile

occurs in serpentine. The individual fibres are not so strong as the white, nor are they so flexible. Their length again is as the length of the vein which they compose, and it ranges from $\frac{1}{8}$ to 2 in. Their diameter is roughly twice that of the white fibre, and the specific gravity of the family varies between 2.6 and 3.2.

In general, crocidolite is a hydrated ferrous and ferric silicate, complicated in a manner somewhat similar to chrysotile, by the partial replacement of the iron by sodium, and, to a smaller extent, magnesium, so that the ultimate iron content is about 35%. Its formula is of the type $\text{NaFe}(\text{SiO}_3)_2 \cdot \text{FeSiO}_3 \cdot \text{H}_2\text{O}$. Typical analyses are shown in Table 2.

TABLE 2
Analyses of Crocidolite (Blue) from different Sources

Type	Crocidolite High Grade %	Crocidolite Medium Grade %	Crocidolite Medium Low Grade %
Carbonic Anhydride	—	0.35	1.11
Combined Water	4.50	3.20	—

Magnesium Oxide	2.48	2.10	3.03
Sulphuric Anhydride	—	—	—
Alkali and loss	7.17	5.38	5.24

Under the heading of crocidolite may be included the mineral "amosite." It is a grey or light brown fibre, of the amphibole family, closely allied to crocidolite. The fibres are of good length, but, as they tend to be harsh and brittle, have found little use in industry. Their composition and properties are almost identical with those of crocidolite.

HORNBLLENDE (INCLUDING TREMOLITE, ACTINOLITE, ETC.)

Most of these varieties differ from chrysotile and crocidolite mainly in that they are only semifibrous, and are very friable. They are, in fact, but little removed from the steatites. They are, as a class, white, but liable to much discoloration by ferric and ferrous compounds.

Their use in industry is limited, their most technical use being as filtering media. Their composition is of the type $\text{Ca}(\text{MgFe})_3(\text{SiO}_3)_4$, with the magnesium again partly replaced by iron. A typical analysis shows:—

Carbonic Anhydride	0.87
Combined Water	1.33
Silica	54.89
Alumina	Trace
Iron Oxide (Ferric)	Trace
Iron Oxide (Ferrous)	7.10
Calcium Oxide	12.04
Magnesium Oxide	24.23
Sulphuric Anhydride	—
Alkali, loss	0.04

All three classes have different properties, rendering them peculiarly suitable for different industrial uses. For instance, whilst all three successfully withstand boiling in weak or concentrated alkaline solutions, chrysotile suffers more than crocidolite and other amphiboles when subjected to boiling solutions of the common acids, and loses as much as 60% of its own weight under the severest of conditions (i.e., boiling in concentrated hydrochloric acid), whereas the others lose only 5% to 15% and that nearly all adherent impurity. Thus, for chemical engineering purposes, where the fibre has to withstand such treatment, it is possible to prepare, by previous acid washing, a cloth from amphibole asbestos, which will lose no more on further immersion.

The most important property of the fibres, however, is their ability to maintain their fibrous state and physical strength when subjected to high temperatures.

Asbestos is a crystalline formation, and each class has a fairly uniform content of water of crystallisation. The higher that content, the better the physical strength and flexibility—and correspondingly the more desirable to the spinner and weaver. The chrysotile family contains from 10% to 15% combined water, crocidolite from 4% to 10%, and hornblende from 0.5% to 1.5%. It has been established definitely that as asbestos loses its combined water (as distinct from ordinary adsorbed moisture), it simultaneously loses its physical strength and proceeds towards the amorphous friable state. Or, in other words, so long as it is not subjected to such a high temperature that it loses its water of crystallisation, its strength and fibrous character remain unimpaired. It follows then that the true merit of the asbestos types from various sources, depends mainly on the temperature at which dehydration commences. Several observers have recorded their findings, and they appear fairly unanimous.

Kersting in 1898¹ noted that high grade chrysotile heated at 1000° C. in a muffle became a little more brittle. Chrysotile of lower grade similarly treated became very brittle. Crocidolite heated at 1000° C. in a muffle broke down to a hard red powder. He concludes that crocidolite would be useless in places where the temperature ever rose to more than 200° C.

Van der Bellen² in 1900 determined the fusion point of fibre with high water of combination at 1550° C. to 1570° C., and of fibre with low water of combination at 1150° C.

Bobaricov in 1916³ observed that Russian chrysotile lost its combined water, and incidentally its strength, at from 500° to 700° C.

Bayer in 1916⁴, in an investigation for the purposes of testing the strength of asbestos at high temperatures, the influence of cotton content, and the heat insulating property of asbestos boards and mattresses, found that chrysotile does not change perceptibly in strength when exposed to 400° C., whereas the results of similar tests on South African blue indicated that it should not be used for insulation above 200° C., because it loses greatly in strength on exposure to high temperatures.

Henry Joseph⁵ tested chrysotile from various sources, and reports that they behave similarly in that they begin to lose their combined water at 450° C., and are completely dehydrated at 800° C. Crocidolite began to change below 300° C., and at the end of 1 hr. at 350° its fibrous character and strength were completely destroyed. The fusion points after dehydration he fixes at 1500° C. for Russian chrysotile, 1540° C. for Canadian chrysotile, and 1150° C. crocidolite.

The writer's investigations confirm Joseph's report, and establish that all types of chrysotile begin to dehy-

drate at 450° C., and that 1 hr. at 850° C. suffices to dehydrate completely. Crocidolite from one source commences to dehydrate at 322° C., from a second source at 382° C., and 1 hr. at 540° C. and 600° C. respectively suffices to dehydrate completely.

Against the above reports we have the article in this JOURNAL (CHEM. & IND., Aug. 7, 1925, p. 796), which states that blue asbestos will withstand a temperature of 425° C. indefinitely, and infers that chrysotile will not withstand a temperature much above 315° C. It has been definitely proved that this is not so, for, as recorded above, investigators are unanimous in stating that chrysotile does not begin to dehydrate until 450° C. is reached, no matter what its source; whereas crocidolite is not dependable above certain much lower temperatures, variously fixed at from 200° C. to 382° C.

The breakdown temperatures given above were all determined on crude fibre alone. The writer attempted to obtain confirmatory figures using spun and woven materials. A tubular electric furnace was inserted in a planished steel tube, wrapped with these woven materials. A pyrometer was inserted in the furnace tube. The fabrics were prepared in suitable form (frayed down to 1 in. of warp threads) so that the strength before and after heating might be determined. The results are tabulated. The specimens were heated under such conditions as obtain on steam pipe covering, and the temperatures refer to the heat of the steam in the pipe round which the specimens were wrapped. Each figure is an average of twelve test pieces.

TABLE 3

Showing effect of increasing temperature on white and blue asbestos fabrics

Per cent. original strength remaining after heating for :—	Chrysotile (White)	Crocidolite (South African Blue)
1 h. at 200° C.	100%	100%
1 h. at 300° C.	100	100
	100%	90%
1 h.	100	62%
3 h's. at 500° C.	100	40%

There are other features on which suitability for heat insulation purposes depends. In boiler mattresses, for instance, crocidolite being of a harsh springy nature, does not fall so closely together as does chrysotile, and, in consequence, makes a rather bulkier mattress for its weight; the mattress, having more air spaces, also tends to be rather more efficient from the point of view of specific insulation.

A disadvantage of the blue fibre is that it is largely a "ferrous" compound, and is, therefore, comparatively unstable. It is liable to oxidise under certain warm, damp conditions, and oxidation is accompanied by disintegration and loss of fibrous strength. In all cases where the conditions are such as encourage oxidation, it is preferable to use white fibre.

The harsh and springy nature of blue asbestos precludes its use in stuffing boxes and in lubricative packings.

Another desirable property is that of mechanical strength and ability to withstand abrasion and accidental damage. Weight for weight, a chrysotile yarn is much stronger than crocidolite, and can be spun more smoothly, and is more uniform in section.

THE CHEMISTRY OF CELLULOSE*

The widespread occurrence of cellulose, the substance contained in the cell walls of plants, as well as the vast number of industrial uses to which it is put, renders this organic material one of the most fascinating from the point of view of the chemist. One has only to enumerate the industries which are dependent on cellulose for their existence to be assured of the great service which it gives to mankind. The cotton industry, with its related branches of bleaching, dyeing and finishing, the manufacture of paper, artificial silk, explosives, such as cordite, all go to this source for their raw material; nor should it be forgotten that the coal measures owe their existence to a pre-existing vegetation in which cellulose was largely represented, whilst the possibility of the use of waste cellulosic materials, such as sawdust for the production of industrial alcohol, is now one of the live topics of the day.

The name cellulose indicates the organised structure of the substance, which is usually found in the form of fibres in the vegetable world, and no study of the chemistry of this product would be complete without an adequate examination of its physical properties also. It is, indeed, a colloid, and most of its industrial uses depend on its fibrous or colloidal nature. Analysis reveals the empirical formula as $C_6H_{10}O_5$, but as the molecular weight is exceedingly large this must be multiplied by an unknown factor x . In each of these simple residues there are three free hydroxyl groups which take part in the esterification processes known as nitration, leading to nitro-cellulose or gun-cotton, and acetylation with the formation of cellulose acetate silk or films. Similarly, a trimethyl cellulose is known.

In the presence of alkali, cellulose combines with carbon disulphide to give a xanthogenate, soluble in water, which represents the first stage in the process of the manufacture of viscose silk; whilst the complete solubility of cellulose in cuprammonium solution affords still another method by which extruded filaments of pure cellulose can be obtained.

On complete hydrolysis with dilute sulphuric acid, cellulose is converted almost completely into glucose. Another simple method by which cellulose can be degraded is by acetolysis, which converts cellulose to the extent of 30% into cellobiose. Workers in this laboratory† have recently advanced experimental proof of a new formula for glucose, representing it as a substituted amylene oxide, *i.e.*, a six-membered ring containing five carbons and one oxygen, coupled with other addenda. The constitution of cellobiose has also been definitely determined.

Here then we have valuable information which serves as a preliminary to the new effective study of the constitution of this polysaccharide. It follows that the linkages with the other residues must involve the first and fourth carbon atoms of the $C_6H_{10}O_5$ unit, but even with the problem simplified to this degree, several modes of combination to give a complete cellulose molecule are possible, and various workers, on the basis of our earlier results, have suggested that the

cellulose molecule is represented by a repetition of cellobiose units joined to give either a cyclic form or long-extended chains, but the experimental basis for these assumptions is lacking.

Recent work by Hess has given rise to the conception that the linkages between one glucose residue and another are effected by residual valencies, and not by principal valencies. It must, however, be confessed that at present we know little experimentally on the subject of residual valencies, and on the whole it seems an inadequate representation to suggest that so stable a substance as cellulose should be built up on this plan. Indeed, from work recently done in this laboratory,† it would appear that in the simplest possible case that we could study, principal and not residual valencies are involved in polymerisation of simple to higher molecules, a conclusion which is also reached in the valuable work of Staudinger.

Fortunately, the chemist has at hand a valuable instrument of enquiry in the X-ray spectrograph. Knowing the facts so far ascertained as to the constitution of the simplest units, it is possible to utilise these in an interpretation of the X-ray data. Sponner and Dore have shown that the amylene oxide formula of glucose is in perfect agreement with the requirements of the X-ray measurements. The distance between units agrees with the required length to within 1%. Again, the arrangement of these units in the space lattice corresponds on the X-ray diagram with the intensity of the spacing represented by the actual positions of the carbon and oxygen atoms at their greatest density.

The arrangement of the glucose units proposed by these authors differs from that found in the cellobiose structure. They suggest that the linking of the glucose residues occurs through the reducing groups of position (1) of one pair and the groups of position (4) of the second pair, and that this arrangement is repeated throughout the whole pattern along the total length of the fibre. This brings the layers of the long chains of glucose units into positions which are consistent with the views derived from plant physiology that concentric layers are successively deposited from within the tube by the protoplasm of the cell.

Thus by combination of the methods of structural chemistry with those available by the use of the X-ray, attempts are being made to obtain a satisfactory structure for cellulose.

CANADIAN MINING AND METALLURGY

Quebec's second smelter will be built at Gros Pin, near Quebec, on land recently purchased by the Shawinigan Water and Power Co. The site for another smelter, to refine ores from Gaspé (zinc) Eastern Townships and Chibougaou, has not been definitely decided, but will undoubtedly be at a point where cheap power is available, and probably water transportation facilities. The Noranda smelter will serve the Rouen district.

The Ladysmith smelter, which has been idle for some years, has passed into the control of a subsidiary of the British Metals Corporation, and will be operated. Mining properties are being secured on the Portland Canal district to provide a regular supply of ore to the smelter, independent of customs shippers.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

EXTENSION OF PERIOD FOR REDUCED RAILWAY FARES

Since the programme for the Annual Meeting was printed, the Railway Companies of Great Britain which agreed to issue tickets at the ordinary single fare and one third for the double journey to persons travelling to Edinburgh to attend the meeting have extended the validity of these tickets, and they will be available from Saturday, July 2, to Monday, July 11. These tickets will be obtainable at the time of booking on production of vouchers which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

It is urgently requested* that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

PROPOSED EXCURSION TO ST. ANDREWS ON SATURDAY, JULY 9

The train will leave the Waverley Station, Edinburgh, at 9.30 a.m., arriving at St. Andrews at 11.22 a.m.

A visit to the University, including the Chemical Laboratories, will be arranged for the afternoon, and the St. Andrews University Court has kindly offered to entertain the members to tea in the University Buildings.

The return train will leave St. Andrews at 5.35 p.m., arriving in Edinburgh at 7.26 p.m.

Members will also have an opportunity of visiting other places of historic interest in St. Andrews or of playing golf.

OTTAWA SECTION

The annual meeting, held on May 19, at the University Club, was preceded by dinner at the same place with Mr. A. E. MacRae in the chair on both occasions. The secretary, Mr. R. D. Whitmore, presented a report of the year's progress showing that the section has advanced in a very satisfactory manner.

The following officers and committee-members were elected:—Chairman, Frank T. Shutt, M.A., D.Sc., F.I.C., Dominion Chemist and Assistant Director, Dominion Experimental Farms. Secretary, Mr. R. D. Whitmore. Executive Committee: Messrs. F. E. Lathe, A. K. Light and Clayton E. Watson, full members; Miss S. E. Wright and Mr. J. W. Davy, associate members. Auditors, Messrs. J. Dick and M. C. Fletcher. Trustee for Queen's Prize Fund, Dr. A. E. Macintyre.

The retiring chairman, Mr. A. E. MacRae, before presenting an address entitled "Patents, with particular reference to the public service," spent a few moments on an explanatory account of the Pan-American Union, indicating how Canada might be affected industrially and otherwise.

Returning to the subject of patents, the speaker first showed the distinction that the authorities endeavour to draw between what is merely a discovery and what is really an invention. Only the latter may be patented.

Basic principles or inherent, natural properties of matter cannot rightly be patented; new processes or new products can be. A new idea, and that idea then put into practice, are the two mutually dependent parts which constitute an invention, and one is useless without the other. The foregoing points were supported by quotations from judgments handed down by legal authorities and by concrete examples of patents granted, refused and disputed.

An amendment of 1923 to the Patent Act has placed members of the public service of Canada in a very favourable position. The civil servant may not expect such a full reward as an independent inventor because the former has used public time and money. Should such an invention be of use to a Government department, either the inventor or his department may obtain a Canadian patent, when the Canadian royalties are paid, half to the State and half to the inventor. The latter remains free to patent his invention in foreign countries and receive to himself all royalties from these sources.

Mr. MacRae noted that patentable ideas arising in the course of departmental research are often not published. In the course of time the same idea is perhaps patented independently by an individual outside of the civil service. The public has then to pay royalties on something already invented and paid for in public time and money. Therefore he would urge all departments who do not wish to obtain patents to at least publish the work and so render it unpatentable to others.

The Ottawa section is largely composed of civil servants who, at this meeting, showed their very considerable interest by a number of questions. Dr. F. T. Shutt, as chairman-elect, conveyed the thanks of the meeting to Mr. MacRae both for his address and for his splendid services through the past two years.

Attention was directed to the annual meeting of the Society to be held in New York in 1928, and the hope was expressed that Ottawa would be visited by those intending to be at that meeting from the British Isles.

YORKSHIRE SECTION

The annual meeting was held at the Great Northern Hotel, Leeds, on May 2. Mr. H. J. Hodsmen, the Vice-Chairman, who presided, alluded to the serious illness and long absence of Mr. B. A. Burrell, whose term of office as chairman was due to expire, and the Section expressed its gratitude for Mr. Burrell's services and their best wishes for his early recovery.

Officers and new members of Committee were elected for the ensuing Session as follows:—Chairman, Mr. H. J. Hodsmen; Vice-Chairman, Mr. W. B. Hill; Honorary Secretary and Treasurer, Prof. N. M. Comber; and Committee, Mr. B. A. Burrell, Mr. C. P. Finn, Prof. F. M. Rowe, Mr. J. A. Reddie, and Mr. J. B. Speakman.

Following the business, Prof. N. M. Comber read a paper on "Soil formation processes and the foundation of a new subject."

The chemistry of soils was far from simple, and in spite of the big advances made during the last fifteen years or so, a great deal of the fundamental chemistry of the soil still remained obscure. Indeed, it was quite likely that the state of our knowledge of general chemistry was a

limiting factor to the development of soil chemistry. Almost every new development in physical chemistry seemed to throw fresh light upon soil problems. As men of science gave more attention to the soil, not only did it become apparent that the higher ramifications of physical colloid and organic chemistry were involved, but also that microbiology and physics were involved along with chemistry in the study of soil fertility.

It was not unnatural, therefore, that the segregation of the science of the soil as a special subject, so to speak, with a name of its own, was suggested in various quarters. The suggestions first put forward did not receive a very warm welcome and were, in fact, opposed by some students of the soil in this country. Such opposition was quite sound, for the application of a particular science or several sciences to an industrial problem does not necessarily constitute a new subject.

In recent years, however, the outlook had been considerably changed by the outstanding work of the Russian School. It could fairly be claimed that the study of soil formation processes had given to Soil Science a fundamental characteristic which had been properly recognised by the adoption of the word *Pedology* to describe the science of the soil. The work of Sibirtzev, Glinka, Stebut, and others had put the backbone into the study of soils and turned that study into Pedology in the same way that William Smith put the backbone into the study of rocks and made it Geology.

The word Pedology had been almost unanimously accepted on the Continent and to a large extent in America, but in this country there were several eminent pedologists who were still reluctant to admit that description of themselves.

The chairman, in opening the discussion, remarked that the leaching of bases from clays was a matter of great importance in the manufacture of the refractories and ceramic materials, and that it was practically impossible to make refractory materials from clays that were half leached. Questions were raised by several members as to the effect of the leaching of bases from grassland upon the reaction of the soil, and the effect of this reaction upon the type of herbage which developed.

Prof. Comber, in replying, pointed out that the control of the reaction of grassland had to be considered in connexion with the purpose to which the grassland was to be put. The farmer, who was concerned with the feeding quality of the grass, was usually advised to counteract acidity by liming, in order to develop the more nutritive grasses, and particularly to develop clover, and so increase nitrogen. On the other hand, for playing fields and particularly golf greens, quite different considerations arise, and the wearing properties of the grass are most important. It was a great mistake to lime golf greens, which so far as existing work indicated, were best developed at a $p_H = 4$, or thereabouts. The majority of golf greens in this country were probably not sufficiently acid to admit of the satisfactory development of the particular grasses required.

The Calendar of Forthcoming Events will be found on p. 534, column 1.

CHEMICAL SOCIETY

At a meeting held on June 2, the President, Prof. H. Brereton Baker, C.B.E., F.R.S., occupying [the Chair, Mr. U. R. Evans discussed:—

The Passivity of Metals. Part I. The Isolation of the Protective Film.

When vacuum-fused electrolytic iron is rendered passive in potassium chromate solution, and then subjected to anodic treatment in sodium chloride solution, the metal is dissolved away, leaving (along with certain secondary products) a transparent envelope which retains the shape of the original specimen. A transparent skin can also be removed from passive iron by dissolving out the metal from below by means of iodine. The same method can be used to remove the visible films responsible for the temper-colours of heat-tinted iron; in all cases the transparent films consist of ferric oxide. Relatively thick (visible) films tend to crack and are non-protective, whilst the films produced by unduly short exposure of cold iron to air are discontinuous. To produce passivity, the films must be continuous. The films responsible for passivity possess thicknesses too small to show interference tints, but the thickness varies with the conditions of production, and particularly with the presence of internal stresses in the metal, which tend to cause cracking and thus allow the films to thicken locally; the thickness varies considerably from point to point. (Chlorides favour the activation of passive iron, because chlorine ions can pass through the membrane, and under anodic conditions the metal is dissolved away below the skin, which becomes loosened; mere immersion in a chloride solution, under conditions which preclude the flow of local currents, causes no reversion to activity. The rather unreliable passivity produced in electrolytic iron by nitric acid has been investigated. Transparent films have been isolated from the surface of passive copper and aluminium.

The President asked whether the author was satisfied that the film consisted entirely of ferric oxide, and not ferrosferric oxide. When iron is rendered passive with steam ferrosferric oxide is formed, and, moreover, iron made passive with nitric acid loses its passivity on local heating. Treatment of the film with iodine or anodic chlorine might oxidise ferrosferric oxide to ferric oxide.

Dr. W. H. Hatfield emphasised the industrial interest and importance of investigations on passivity. It was not very long ago that resistant steels were made by rule-of-thumb methods. The speaker referred to the case of steel containing 14% Cr, which after suitable heat treatment is "stainless," and to its occasional failure to possess its normal resistance to oxidation.

Dr. Bengough remarked that confusion resulted from the use of the term "passivity" to describe different phenomena. The corrosion of pure iron in water containing a little chloride could be ascribed to the penetration of a passive film by chlorine ions.

Dr. W. H. J. Vernon said that the accumulated evidence showed that the films obtained with liquid reagents are identical with those produced by direct oxidation; thus copper rendered passive by chromate

solution or exposure to air lost its considerable immunity from tarnishing on treatment with ammonium chloride solution. By actually isolating thin oxide films the author had provided the most direct evidence regarding the nature of the process.

Mr. Evans replied that within the period allowed, iodine does not oxidise magnetite to ferric oxide. It was certain that the film on the air-passive region was ferric oxide; the film produced at higher temperatures is magnetite, both films being formed at intermediate temperatures. The films were distinct in appearance and properties. In reply to Prof. Bassett he said that the thickness of the film varies with the conditions of production from about 400 Å. probably to unimolecular thickness. The essential condition for passivity is that the film must be continuous.

Prof. T. M. Lowry contributed the following paper:—

Studies of Valency. Part VIII. The Molecular Structure of Vernon's Dimethyltelluronium Salts. [With (Mrs.) R. R. Goldstein.]

(a) The absorption of Vernon's dimethyltelluronium halides increases progressively from α - TeMe_2Cl_2 to α - TeMe_2I_4 . The α - and β -dibromides each show a marked step out; the α - and β -diiodides and the α -tetraiodide show the twin maxima already recorded in CH_3I and in KI_3 . The results are in harmony with a suggestion, derived from the electronic theory of valency, that only one halogen can be ionised at a time, as in the formula $[\text{TeMe}_2\text{X}]^+\bar{\text{X}}$.

(b) The dihalides give conductivities which indicate that one halogen is hydrolysed more or less completely, whilst the other persists as a halogen ion $[\text{TeMe}_2\text{X}]^+\bar{\text{X}} \rightleftharpoons [\text{TeMe}_2\text{OH}]^+\bar{\text{X}} + \text{HX}$. The hydroxy-halide itself undergoes a partial hydrolysis, however, when one equivalent of acid is removed from the solution, although silver oxide must be used in order to liberate the free base $[\text{TeMe}_2\text{OH}]^+\bar{\text{X}} \rightleftharpoons [\text{TeMe}_2\text{O}]^+ + \text{HX}$.

(c) In the quadrivalent compounds of tellurium, the third valency is a covalency and the fourth valency is an electrovalency. Similarly, in the quinquevalent compounds of phosphorus, arsenic and antimony, the fourth valency is a covalency and the fifth an electrovalency. In general it appears that, whenever the normal valency of an element is increased by two units, one of the additional valencies is a covalency, and the other is an electrovalency.

The President asked whether the compounds described as Vernon's were not, in fact, first prepared much earlier by Dr. Alexander Scott. The late Dr. R. H. Vernon had never claimed the credit of their discovery.

Dr. S. Sudgen said that two of the three substances giving the characteristic iodoform curve could readily be formulated by the theory of singlet linkings (J., 1927, 1174) as:

The iodides of the telluronium bases are feebly hydro-

lysed and dissociated even at high dilutions in water, and some non-ionised formula seemed to be required for the substances in the free state or possibly in a non-ionising solvent.

Prof. Lowry replied that he had associated Vernon's name with the compounds under examination because that investigator had first shown that they form both α - and β -series. In reply to Prof. Bassett, Prof. Lowry said that for the absorption spectra the compounds were dissolved in alcohol, whereas for the conductivities they were dissolved in a little alcohol and then largely diluted with water.

Dr. E. E. Turner discussed:—

Factors controlling the Formation of Some Derivatives of Quinoline, and a New Aspect of the Problem of Substitution in the Quinoline Series. [With E. Roberts.]

The effect of substituents in the aniline-residue on the conversion of compounds of type 1 (a or b) into substituted 2:4-dimethylquinolines has been examined.

This condensation is greatly affected by the nature of the substituent. The effect produced is apparently due partly to the directive influence of the substituent, and partly to an influence it produces corresponding with its influence in diminishing the basicity of the aniline molecule when present as a substituent in the latter. Thus, provided one strongly *ortho-para* directing group is present in position 3 (\equiv 5) in I, ring closure readily occurs, even if a second similar group is present in the unfavourable positions. On the other hand, of the three anils derived from the chloroanilines, only the *meta* compound undergoes the condensation, whilst of the anils derived from 2:4-, 2:5-, 3:5- and 3:4-dichloroaniline, only the last has been converted into a quinoline derivative. The non-condensation of the 3:5-compound shows that steric factors may operate.

The Beyer method of quinoline synthesis is also influenced by steric factors, which do not appear to operate in the Skraup and Doebner-Miller syntheses.

The nitration of 2:4-dimethylquinoline and of a number of its chloro-derivatives leads to a new conception of the essential quinoline molecule which exhibits a marked resemblance to the naphthalene molecule, and is well represented by (II).

Substitution in the quinoline series is not controlled by the nitrogen atom, but simply by 5:8 reactivity, corresponding with the reactivity of the four α -positions in naphthalene. In substituted quinolines, 5:8 reactivity has as much orienting effect as the substituent itself, at any rate in the cases of Cl, Me and NO_2 .

The constitution of the anils (Ia or b) is discussed.

In reply to Prof. J. T. Hewitt, Dr. Turner said that nitration of 2-chloronaphthalene yields the 7-nitro-compound, the nitro-group entering the second ring.

SOCIETY OF GLASS TECHNOLOGY

Meetings were held in University College, London, on May 18 and 19, the President, Mr. W. Butterworth, Senr., M.A., in the chair. On the evening of May 18 the annual dinner was held in the Hotel Cecil, London, and during the morning of May 19 a visit took place to the Lamp Works of the General Electric Co., Ltd., at Brook Green, Hammersmith.

At the meeting on the afternoon of May 18 the following three papers were presented:—

"The decomposition of glass by water at high temperatures and pressures," by Dr. G. W. Morey and Dr. N. L. Bowen.—The glasses were heated with water in steel bombs for about 20 hrs. The bomb was then cooled and the product examined. In the case of optical glasses it was found that the barium glasses presented a consistent picture. The amount of attack was greatest with a light barium crown, and least with the very dense barium crowns which were remarkably resistant. The lead glasses as a whole showed a consistent and interesting relation between composition and resistivity. With small PbO content, as in the "soft crowns" or extra light flints, the glasses were badly decomposed at 300° C. and practically completely at 550°. As the lead content was increased, the glasses rapidly improved, the extra dense flints showing remarkable resistance towards water. Of all the glasses tested, a high lead glass was the most resistant to the action of water under the extreme conditions tested. In addition to the optical glasses, several commercial glasses, in the form of pieces of tubing, were subjected to a similar treatment, at the same temperatures. Jena combustion tubing withstood the action of water best, whilst the failure of Pyrex glass was outstanding. At lower temperatures the Pyrex was exceedingly good, but at the higher temperatures of the experiments the boric oxide was completely extracted. The crystals obtained with Pyrex glass at 520° were unknown, but were of particular interest, and their composition was being studied.

"The brittleness of opal glass," by Prof. Dr. G. Gehlhoff and Dr. M. Thomas.—For the determination of the impact strength a special apparatus was described; and Winkelmann & Schott's method was modified by using pebbled balls instead of ground and polished cubes. A dense opal glass containing much fluoride was used, the opacity being increased by the addition of zinc oxide. It was found that at a temperature of about 1040° C. some discontinuous changes took place, possibly explainable in the following way. At high temperatures the opal glass was clear. In cooling down, crystals of a uniform and small size of grain were precipitated. The glass kept below the devitrification temperature already contained (owing to its having stood longer) bigger crystals. On further cooling down, in conformity with the law of the yet undefined constitution diagram, small crystals were precipitated, whereas the existing big ones still grew. It might appear feasible that the opal-glass, containing only crystals of a uniform and small size, possessed greater mechanical strength than a glass consisting of crystals of various sizes, particularly larger ones. The investigation showed that opal glasses must necessarily be worked above the temperature where

precipitation of crystals caused opacity of the glass: it was suspected (from work being done) that similar phenomena held good in respect of clear glass.

"The new British 15-arm automatic suction bottle machine," by Francis Redfern, Junr.—This machine is composed of 15 separate bottle-making units, each complete in itself. There are approximately 40 tons of moving parts mounted on the stationary element, and the whole machine weighs about 60 tons. It will revolve up to speeds of between 6 and 7 revolutions a minute, and is electrically controlled. By means of an electromagnetic brake automatically applied it can be brought to rest from a speed of 6 revolutions a minute within 2½ ft. To accommodate the machine to the level of the pot, or the glass in it, it is raised or lowered by a small motor which is cut out automatically at the highest and lowest positions. At 6 revolutions a minute, the machine takes about 11½ horse-power to revolve it. The machine is constructed in such a way that it is possible to sit inside it while it works. The range in length of bottles (measured from the bottom to the parting line below the ring) which can be manufactured on the machine is from 15 in. to 2½ in., for a maximum diameter of blow mould of 9 in. and of parison moulds of 7 in. Wide mouth ware can be made in which the maximum outside diameter of the neck mould is 5¼ in., and the maximum length of plunger which can be inserted into the bottle is 2½ in. A week's production of merchantable reputed quart bottles is estimated at 2,800 gross. The machine can be produced in three sizes, 6 units, 10 units and 15 units. It was possible to make on it, at one and the same time, 6 different bottles all of different shapes, varying in height within a difference of 3½ in. Bottles varying in weight by 4 ozs. have been made on a 10-arm machine.

The meeting on the afternoon of May 19 was devoted to a discussion of *Furnace efficiency*. The discussion was opened by Prof. W. E. S. Turner, who gave a *résumé* of the paper he had presented at the April meeting, namely, "A brief review of furnace developments."

Mr. B. P. Dudding and Mr. E. A. Coad-Pryor suggested that the discussion be focussed under the following headings:—(a) Load-fuel consumption; (b) Age of tank; (c) Load and effect on total life; (d) Maximum efficient load; (e) Composition of the glass; (f) External conditions of all kinds, such as contour of neighbouring country, prevailing wind, etc.; (g) General design—ports, bridges, melting areas, etc. At the suggestion of Mr. J. H. Webster a further heading was added, namely, (h) The method of control of gas and air. Mr. Webster observed that too many pot furnaces and tanks suffered from insufficient control. It was quite a common thing to find neither gas nor air control. The question of the number of dog holes was under consideration. He had seen tanks with as many as four and the introduction of four was an easy proportion and could assist in overcoming those imaginary currents which were said to be set up in tanks having one dog hole. With regard to heat losses, these were discovered at three important places: (1) Producer, 17%; (2) furnace structure, 40%, and (3) chimney flues, 28%; 15% seemed to be the best figure obtained for heat utilised in actual practice. Reference was also made to waste heat boilers and to powdered fuel.

PERSONAL AND OTHER ITEMS

The official list of honours conferred by the King on the occasion of his 62nd birthday includes the following names:—Mr. R. J. Neville Neville, J.P., M.P., at one time chairman of the Brentford Gas Company, becomes a baronet; and Prof. C. J. Martin, C.M.G., D.Sc., F.R.S., Director of the Lister Institute, and Mr. E. Davis (in recognition of his services in connexion with the development of the mineral resources of the Empire) become knights. The Order of Merit is conferred on the Hon. Sir Charles Parsons, K.C.B., F.R.S., in recognition of his eminent services in scientific research and its industrial application. Sir Frank Heath, K.C.B., late Secretary to the Department of Scientific and Industrial Research, becomes G.B.E., as does Sir Richard Threlfall, K.B.E., F.R.S., in recognition of his public services. The honour of C.B.E. is conferred upon Mr. D. D. Davis, Government Analyst, Newfoundland, Mr. G. M. Stuart (for services in connexion with the Imperial College of Tropical Agriculture), and Mr. J. A. Jameson, Fields Manager of the Anglo-Persian Oil Company. Mr. John Crompton, chairman of the Council of the Textile Institute, receives the O.B.E.

The Ministry of Agriculture and Fisheries announces that Sir Daniel Hall has retired from the post of Director-General of the Intelligence Department of the Ministry, which will now lapse. At the request of the Minister, Sir Daniel Hall has agreed to continue as the Ministry's Chief Scientific Adviser in a part-time capacity, and he will retain the chairmanship of the Research Council.

Prof. Sir J. J. Thomson has been awarded the Mascart medal of the French Society of Electricians, which is given every three years.

On June 7, Prof. A. Smithells, C.M.G., F.R.S., spoke from the London and Daventry stations of the British Broadcasting Corporation, on "How it's done—The manufacture of gas."

Sir Donald MacAlister, K.C.B., and Sir Otto Beit have been reappointed members, and Lord Rayleigh, F.R.S., is appointed a member, of the Governing Body of the Imperial College of Science and Technology.

Dr. H. Houlston Morgan, past-president of the Oil and Colour Chemists' Association, and Dr. C. L. Parson, Secretary of the American Chemical Society, were guests at a dinner of the newly-formed Paint and Varnish Division of the American Chemical Society.

Sir Richard Tetley Glazebrook, K.C.B., F.R.S., has been appointed, by Order of Council dated May 26, 1927, to be a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

At the Annual Degree Congregation of Birmingham University on July 2, the honorary degree of LL.D. will be conferred upon Dr. Arthur Lapworth, F.R.S., professor of chemistry in the University of Manchester.

At the Oxford Encenia, on June 30, it will be proposed to confer the honorary degree of D.Sc. upon Sir Robert Hadfield, Bart., D.Sc., F.R.S., and upon Dr. R. Willstätter, professor of chemistry in the University of Munich.

Prof. F. G. Donnan, C.B.E., F.R.S., has been elected a member of the Royal Academy of Sciences of Amsterdam, thus filling the vacancy caused by the death of Prof. Golgi.

Dr. E. H. Archibald, head of the department of chemistry at the University of British Columbia, has resigned owing to ill-health. He will, however, continue as professor of analytical chemistry. Dr. R. H. Clark, associate professor, has been selected as the new head of the department.

Dr. M. J. Marshall has been appointed associate professor of chemistry at the University of British Columbia.

Prof. J. M. Eder, whose retirement from official duties is announced, has been awarded a large gold medal by the President of Austria for his services to the Republic. Prof. Eder has also been awarded the Peligot Medal of the French Photographic Society in recognition of his numerous contributions to technical and scientific photography.

An 1851 Exhibition senior studentship for biochemistry has been awarded to Mr. R. Hill, M.A., at Cambridge. At Emmanuel College, Mr. C. Rimington has been awarded a Sudbury-Hardyman Prize of £20 for a dissertation on a biochemical subject.

Mr. T. Hopkins, M.Sc., has been awarded the degree of Ph.D., by the University of London for a thesis describing a new type of dyestuff.

Mr. J. A. Singmaster, General Manager, Technical Department, and Mr. F. G. Breyer, Chief of Research, have resigned their positions with the New Jersey Zinc Company, and opened a consulting office at 1640, Graybar Building, 420, Lexington Avenue, New York.

Fire destroyed patterns and other stock and several buildings of the Mirrlees Watson Company, engineers, Scotland Street, Glasgow, on June 6. The damage is estimated at £20,000.

We regret to learn of the death of Prof. W. C. Williams, B.Sc., who was professor of chemistry at the University of Sheffield from 1883 to 1904.

We regret to learn of the death of Mr. A. B. Reckitt, managing director of Reckitt & Sons, Ltd.

Mr. T. W. Stainer Hutchins, managing director of Electro Bleach & By-products, Ltd., Middlewich, has died at the early age of 47.

Dyestuffs Licensing Committee

By a unanimous vote the Dyestuffs Licensing Committee, on which both the users and the manufacturers of dyes in this country are represented, has recommended that licences for the importation of foreign dyes may be granted from September 1 in respect of those dyes for which British producers demand over twice as much as the pre-war price. Hitherto the price factor imposed by the committee was two-and-a-half times the pre-war figure. In view of this decision, it seems probable that the price of British dyestuffs will undergo an equivalent reduction of 20%. The imports of dyes are mainly dyes which are not made in this country, as the British dyestuffs industry has captured the greater part of the home market.

The Explosives Industry

The 51st annual report of H.M. Inspectors of Explosives, for the year 1926 [Cmd. 2871, H.M. Stationery Office, price 9d. net], states that the total number of factories is now 101, two new factories having been established and five having become extinct. Two new licences and 55 amending licences were issued. There are also 20 toy firework factories and five small firework factories. The total number of accidents generally in connexion with explosives reported during the year was 276, causing 36 deaths and injury to 269 persons. The number was less than usual on account of the smaller number of blasting accidents owing to the coal mines having been closed for several months.

It is noted that by the passing of the Petroleum Act, 1926, H.M. Inspectors of Explosives have now a definite status under the Petroleum Acts.

Opening of the New Science School at Clifton College

Through the generosity of Old Cliftonians, who have already subscribed four-fifths of the requisite total of £50,000, a handsome new Science School has been erected at Clifton College. The building was formally opened on June 2 by H.R.H. The Prince of Wales, who emphasized the value of science to the community and expressed the hope that the college would prove the cradle of future Kelvins, Faradays, and Tildens. The Headmaster, Mr. Norman Whatley, remarked that the new building was to be the home of industry, variety, enterprise and cheerfulness, and hoped that it would not be considered an impertinence for him to suggest that it was most appropriate that a building in which these qualities were to flourish should be opened by His Royal Highness.

The Science School consists of a central block with side wings and contains six laboratories, four lecture rooms and a science library, together with a small biological laboratory, private rooms for research, workshops, polarimeter and dark rooms, preparation rooms, etc. It has been spaciouly designed and equipped according to the most exacting modern ideas, and, to ensure harmony with the rest of the College buildings, it is in a late gothic style of architecture. The architect, who, together with Mr. E. J. Holmyard (Head of the Science Department), and Mr. W. C. Badcock (Head of the Physics Department), had the honour of being presented to His Royal Highness, is Mr. Alan E. Munby.

Among the distinguished visitors at the opening ceremony were the Duke and Duchess of Beaufort, the Marquis of Bath, Field-Marshal Lord Haig (President of the College), Rt. Hon. J. H. Whitley (Speaker of the House of Commons)—through whose instrumentality the necessary funds were raised—Sir Richard Gregory, Sir Richard Threlfall, Sir Thomas Heath, Profs. Hutchinson, Lindemann, Francis, Tyndall, Darbishire, Fawcett and Reynolds, and Mr. F. B. Stead (H.M. Chief Inspector).

The Library, which is a fine room fitted throughout in oak, proved a special centre of attraction. Clifton possesses a large collection of scientific classics, including copies of works by Avogadro, Cannizzaro and Tyndall, with autograph inscriptions by the authors, a MS. volume of Rouelle's lectures, and many first editions of Dalton, Newton, Boyle and other celebrated scientists. Of local interest are "The Ordinall of Alkimy," by Thomas Norton, and a collectaneous volume of the alchemical

writings of Samuel Norton, Thomas's grandson, both Bristolians. The library was further enriched on June 2 by the addition of a photograph of the Prince, which H.R.H. was gracious enough to sign and which is to have the place of honour in memory of the royal inauguration.

Many well-known scientists have taught or been taught in the Clifton Laboratories. Debus, Worthington, Shenstone, Wollaston, Sir William Tilden, Rintoul and, for a short time, Prof. H. B. Baker, come into the former category, while in the latter are included Sir Max Muspratt, Prof. H. H. Turner, Prof. Norman Collie, Sir Richard Gregory, and Prof. A. Hutchinson.

British Non-Ferrous Metals Research Association

The Seventh Annual Report of the British Non-Ferrous Metals Research Association, which has just been issued, describes its work during 1926, which has been carried out at a cost of over £25,000. The report gives details of the 27 researches which have occupied more than forty investigators during the past year. The most diverse problems are being studied, such as atmospheric corrosion, the production of sound castings, locomotive fireboxes, lead pipes, materials for high temperature service and electro-deposition.

In connexion with the Annual Meeting of the Association, a luncheon was held at the Savoy Hotel on May 27. Mr. Thos. Bolton, as Chairman, made an earnest appeal for greater participation and support by all those who use non-ferrous metals and alloys. He pointed out that the Association was lop-sided and needed the co-operation of users, who stood to benefit even more than the producers in prosecuting research for improved materials. The feeling of comradeship which had developed in recent years between competitors in manufacture and between buyer and seller could find no more beneficial scope for its application in the Research Association. Both Mr. Bolton and Sir Alfred Mond, who followed him, emphasised the increasing influence of University trained men in industry; scientific training along broad lines was most important, not only in the research departments, but also on the production side and even in salesmanship.

Sir Alfred Mond urged the importance of research with a wide outlook directed to the development of new processes which do not exist at the present moment. He considered that there was no safer investment in the world than research, and its results would far outweigh the financial expenditure incurred. The prizes in metal research work are great indeed, for all the research work yet done on alloys has only touched the fringe of the subject. For this reason he promised the Association all the support in his power to command.

Sir Frank Heath, in making a last appearance before retiring from his post as Secretary of the Department of Scientific and Industrial Research, urged that research should be looked upon as a form of provision against depreciation. Knowledge, like plant and machinery, must be looked upon as a wasting asset, and new supplies, unlike the latter, could not be bought "off the shelf," but were only available to those who made them their own by active co-operation with the scientific workers who were providing the new knowledge. Sir Frank Heath specially referred to some sections of the metal industry for which the Association has already most valuable results to offer, but where support by the producers has not yet been awakened.

Biochemistry at Birmingham University

The Prime Minister has consented, formally, to open the new Biological Block of the Birmingham University, at Edgbaston, and the extension to Chancellor's Hall, which the Council of the University has fixed to take place on Thursday, October 20. The University will on that occasion confer upon Mr. Baldwin the honorary degree of LL.D. at a special Degree Ceremony to be presided over by the Chancellor of the University, Viscount Cecil. The new Biological Block consists of laboratories and departmental accommodation for the three biological departments—namely, the Department of Brewing and Biochemistry of the Fermentation Industries, Zoology and Botany. The present laboratories at Edmund Street, Birmingham, will be transferred to Edgbaston. The new block will cost, with equipment, over £100,000, and its completion may be regarded as one more stage towards carrying out the original scheme for the University as laid down in 1901. Towards the cost Sir William Waters Butler, who combines the skill of the brewer with that of the chemist, a member of the University Council, has contributed a sum of about £40,000, and the brewing department in the new block will bear his name.

CALENDAR OF FORTHCOMING EVENTS

- June 11. **BIOCHEMICAL SOCIETY.** The Museum, Oxford, at 3 p.m. The following papers will be presented:—(1) "Digestion of carbohydrates in the cockroach," by B. Wigglesworth. (2) "Oxidation of uric acid by hydrogen peroxide." (3) "Estimation of oxalic acid in urine." (4) "Estimation of oxaluric acid in urine," by P. C. Raiment. (5) "Chemistry of phosphagen," by P. and M. G. Eggleton. (6) "The Erlenmeyer amino-acid synthesis," by C. R. Harington and W. McCartney. (7) "Synthesis of vitamin B (torulin) by yeast," by F. Hawking and R. A. Peters. (8) "Use of norite in the concentration of torulin," by H. W. Kinnersley and R. A. Peters. (9) "Presence of a nucleotide in milk," by P. G. Marshall and H. D. Kay. (10) "The peptic digestion of gelatin," by R. M. Beck and R. K. Cannan. (11) "Metabolism of glucose by kidney tissue *in vitro*," by J. T. Irving. The following Demonstrations will be given during the interval for tea:—(1) "A colorimetric method for the determination of the pH of minute amounts of fluid," by V. B. Wigglesworth. (2) "Synthesis of a bacterial growth factor by *Meningococcus*," by J. Orr Ewing and V. B. Reader. (3) "A simple fluorophotometer," by J. H. Jeffree and R. T. Squires (introduced by R. A. Peters).
- June 15. **SOCIETY OF GLASS TECHNOLOGY.** 100th meeting at University, St. George's Square, Sheffield, at 2.30 p.m. (1) "Gaseous fuels for furnace heating," by R. Wigginton. (2) "The thermal expansion of some boric oxide glasses and some remarks on the influence of the inhomogeneity of the glass," by Prof. W. E. S. Turner and F. Winks.
- June 16. **CHEMICAL SOCIETY.** *Ordinary Scientific Meeting.* Burlington House, Piccadilly, W.1, at 8 p.m. (1) "Syntheses of cyclic compounds. Part I. Ethyl- β -dimethyl butane $\alpha\alpha\delta\delta$ -tetracarboxylate and some cyclobutane compounds derived therefrom," by I. Vogel. (2) "A new method of (absolute) potentiometric titration," by B. Cavanagh.

REVIEWS

TRATTATO DI CHIMICA GENERALE ED APPLICATA ALL'INDUSTRIA. By PROF. E. MOLINARI. Vol. I. *Chimica Inorganica*, Pt. II. Fifth edition. Pp. 681—1351. Price 45 lire. Vol. II. *Chimica Organica*, Pt. I. Fourth edition. Pp. xxiii + 660. Price 45 lire. Milan: Ulrico Hoepli.

The issue of the fifth revised and enlarged edition of "Molinari" makes one recall with regret that since it appeared the death of the author has been learned.

The present volume (Part II of Vol. I) completes the section devoted to inorganic chemistry and in it one notes throughout the author's unceasing care to keep the work up to date, much new matter having been incorporated, on subjects such as borax, titanium pigments, decolorising carbons; low-temperature carbonisation, pulverised coal, etc. An attempt has been made to bring the statistics of trade up to date, but the utility of such statistics, is, at least, doubtful.

Part I of Vol. II, devoted to organic chemistry, has now reached its fourth edition, the last revised by its author. No special notice of this part is required, save to note that it contains an obituary of Prof. Molinari, and that the work of revision has been as complete and painstaking as with former volumes. Future editions will be revised by pupils of the author: Prof. Henry, Ing. Chim. Vittorio, and Dr. Alessandro.

"Molinari" is now too widely known to need commendation; its merits have previously received detailed appreciation; and for those who can read Italian, the very moderate price should prove an additional inducement to make the acquaintance of a very useful treatise, which holds the balance between pure and applied science with considerable success.

A TEXT BOOK OF INORGANIC CHEMISTRY. Edited by Dr. J. NEWTON FRIEND, D.Sc., Ph.D. Vol. III. Part II. Beryllium and its Congeners. By JOSHUA C. GREGORY, B.Sc., F.I.C., and MAY SYBIL BURR, D.Sc. Pp. xxvi + 342. London: Charles Griffin & Co., Ltd., 1926. Price 18s.

This volume of the series of text books of inorganic chemistry edited by Dr. J. Newton Friend, deals with the elements beryllium, magnesium, zinc, cadmium and mercury. Chapter I gives an excellent comparative study of the elements dealt with in the following chapters of the book. Each element is discussed in detail under the headings of occurrence, history, preparation, physical and chemical properties, uses and alloys, followed by the preparation and properties of its compounds. A summary of the most important methods for the detection and estimation of the element completes the chapter. In addition there are paragraphs on the purification of zinc, cadmium and mercury, on the electrodeposition of zinc, on the preparation and properties of colloidal cadmium and mercury, and on the physiological action and isotopes of mercury, each of which is to be found in the chapter dealing with the metal concerned. The summary of the processes for the extraction of beryllium compounds from beryl is excellently written, the best conditions for the successful carrying out of the separation from aluminium and the quantity

of residual alumina in the beryllia being clearly stated. The history of the determination of the atomic weight of beryllium is vividly and very interestingly portrayed, as are numerous other studies in succeeding chapters of the book.

The arrangement of the minerals in tabular form, as was done in the earlier volumes of this series, would be an improvement on the present method as being more convenient for reference. It is noticeable that the commercial minerals are not so clearly described as they might be, whilst no mention is made of the very common iron-zinc-sulphide, marmatite. The industrial chemist would appreciate the book more if it contained more manufacturing details, more extensive notes on the alloys and uses of the compounds, coupled with the more liberal use of illustrations and graphs, but as the size of the book is limited, the authors have done the next best thing and supplied an excellent list of up-to-date references from which this information can be obtained.

The book contains very few errors, and these to the trained mind are usually self-evident as, for example, on pages 53 and 54, where it is stated that magnesium hypobromite and bromate are produced by electrolysis of potassium bromide solution; on page 136 that zinc thiochromite is prepared by heating zinc oxide with sulphur in a stream of hydrogen and then in sulphur vapour and on page 45 where it states that the melting point of Mg_2Au is $83^\circ C.$; the last is probably a printer's error.

The authors have, nevertheless, made an excellent summary and many portions of the book show, what is often absent in a compilation such as this, real literary ability.

ALBERT R. LUCAS

HISTORY OF THE SCIENCES IN GRECO-ROMAN ANTIQUITY.

By ARNOLD REYMOND, translated by RUTH GHEURY DE BRAY. Pp. x+246. London: Methuen & Co., Ltd., 1927. Price 7s. 6d.

We are glad to welcome in its English dress this excellent book by Prof. Arnold Reymond (University of Neuchâtel), which was published in French at Paris some three years ago. For a bird's eye view of classical science its only rival is Heiberg's book, and in many ways Reymond gives the better picture. After a short preliminary section on Egyptian and Chaldean science, the author describes in historical sequence the Hellenic, Alexandrian and Greco-Roman periods, passing thence to an account of the principles and methods of the various sciences as understood by contemporaries. As is perhaps only natural, the section on chemistry is extremely short and offers nothing that is new; chemistry in those ancient days was in a state which requires either a page or a series of volumes to describe. The book as a whole is one which can be emphatically recommended to all who are interested in, without being serious students of, the history of science. The translation has been carefully and elegantly made and the general format of the book is good. A school edition at a lower price is desirable, for Prof. Reymond writes in a manner which young people will find very attractive. Any science master who can secure the Classical Sixth for an hour or two a week would find this book admirably adapted for use as a class text-book.

E. J. H.

PARLIAMENTARY NEWS

British Industries Fair

Sir Burton Chadwick informed Lieut.-Commander Kenworthy that it was not proposed to hold the British Industries Fair in provincial cities other than Birmingham in future years. The Committee appointed by the Board of Trade in 1921 to consider the best policy to be adopted in respect of the Fair was opposed to new sections being initiated in other centres besides London and Birmingham.—May 26.

British Celanese Company (Government Representative)

In reply to Mr. E. Brown, Mr. McNeill stated that the Government representative on the board of directors of the British Celanese Company was Sir Philip C. Henriques. He was appointed with the ordinary powers of a director on February 28, 1920, and could not be removed without the consent of the Government so long as the Government held not less than 250,000 preference shares.—May 26.

Oil Imports from Russia

Replying to various questions, Sir B. Chadwick said that in the six months ended April, 1927, imports of Russian refined petroleum, amounted to 62.5 million gallons, and to 31.3 million gallons in the six months ended April, 1926. Imports of crude petroleum from Russia were negligible in both periods.—May 26.

Key Industry Duties

In reply to Mr. H. Williams, Sir P. Cunliffe-Lister said that the following table showed the value of the goods upon which Key Industry Duty was paid during the first four months of the present and previous year:—

Description	January to April, 1926 £	January to April, 1927 £
Optical glass, optical elements and optical instruments	95,778	100,400
Scientific glassware, lamp blown ware and laboratory porcelain	46,641	43,899
Scientific instruments: gauges and measuring instruments of precision	34,620	48,326
Wireless valves and similar rectifiers and vacuum tubes	57,488	44,393
Ignition magnets and permanent magnets	16,438	11,545
Arc-lamp carbons	9,343	6,073
Hosiery latch needles	21,235	22,191
Metallic tungsten, ferro-tungsten, manufactures of metallic tungsten and rare earth compounds	5,760	13,636
Synthetic organic chemicals (other than finished and intermediate organic dyestuffs and colours), fine chemicals and fermentation chemicals	176,375	187,956
Amorphous carbon electrodes	Not dutiable in this period	86
Ferro-molybdenum: ferro-vanadium: molybdenum and vanadium and compounds thereof		
Total of above	463,678	483,958

Gas Mantles

Sir P. Cunliffe-Lister informed Mr. Harris that the Safeguarding duty came into force at the end of December, 1925. The imports of gas mantles during 1925 amounted to 208,902 gross, and in 1926 to 47,708 gross. He was aware that there was an agreement between the largest English manufacturer of these mantles and the German manufacturers with regard to markets. But for the duty, the imports would be quite enormous, and it would be impossible to find a market for our own products.—May 31.

Condensed Milk (Tests)

In a written answer to Major Ainsworth, Mr. Chamberlain said that samples of condensed milk were examined

by the Government chemist and by public analysts to verify that it complied with the standard of composition laid down in the Public Health (Condensed Milk) Regulations, and was otherwise free from adulteration. The tests applied were matters for the discretion of the officers concerned, no standard tests being prescribed.—June 2.

COMPANY NEWS

L. AND N. BROWN COAL, LTD.

Underwriting has now been completed for an issue of £150,000 first mortgage convertible debenture stock in this company, which was formed to purchase 420,000 acres of land in Victoria, Australia, containing deposits of brown coal estimated at over 400,000,000 tons. The company proposes to mine and sell 1,000 tons of raw brown coal daily, and later to distil the coal by the L. and N. process, and to market the oil and residual fuel. The chairman is Lieut.-Col. J. T. Moore-Brabazon, M.P., who is also chairman of the L. and N. Coal Distillation Co., Ltd.

BLEACHERS' ASSOCIATION, LTD.

The trading profits for the year ended March 31, 1927, amounted to £627,906, plus a transfer from reserve for equalisation of dividends of £90,000, making £717,905, compared with £1,066,221 for the previous year. Depreciation fund received £200,000 (same), debenture interest absorbed £101,250 (same), leaving £416,655, plus £294,968 brought in. A final dividend has been recommended on the ordinary shares at the rate of 1s. 2d. per share, making 1s. 6d. per share, carrying forward £711,624.

YORKSHIRE DYEWARE AND CHEMICAL CO., LTD.

The net profit for the year to March 31, 1927, after providing for depreciation and all charges, was £11,736, plus £5,595 brought in, compared with £11,685 for 1925. Interest on debenture stock, less tax, absorbed £4,104. A dividend has been recommended at the rate of $7\frac{1}{2}\%$, making 10%, less tax, carrying forward £1,228.

SANITAS CO., LTD.

The report for the year ended March 31, 1927, shows an available balance, including £1,123 brought forward, of £61,486, compared with £54,008 for 1926. A final dividend has been declared, making 45% for the year, compared with 38.24%, leaving £1,834 to be carried forward.

LIQUID AIR, LTD.

The report covering 15 months ended March 31, 1927, states that after deducting outstanding legal expenses in connexion with the year 1925, now finally disposed of, providing for income tax, depreciation, bad debts, and certain award expenses of a non-recurring nature, the balance available for distribution was £3,668, which the directors consider should be carried forward. For 1925 a dividend of 5%, less tax, was paid and £5,046 carried forward.

SALAR DEL CARMEN NITRATE SYNDICATE, LTD.

The thirtieth annual general meeting was held on June 2, Mr. A. Naylor (chairman) presiding. After referring with great regret to the death of Mr. H. W.

Sillem, the late chairman of the company, Mr. Naylor said the results for the year were very unsatisfactory, but, in view of the condition of the industry, they were not unexpected. The accounts show a net loss of £33,715 for 1926, as against a net profit of £22,199 for 1925. The credit balance of £12,591 brought in is thus converted into a debit balance of £21,126, which has been carried forward. Owing to unsatisfactory sales and to the fact that it had stocks of manufactured nitrate sufficient to meet its expected participation in sales for the nitrate year 1926—27, the company closed down the maquina on April 30, 1926. The maquina had been reconstructed at a cost of £141,996, and was completed in October last year, the necessary funds being provided by an advance from the company's bankers. With regard to the present position and prospects of the industry, under the regulations of the Nitrate Producers' Association, producers have exercised their right to revert to free selling, commencing from April 11 last. It was generally anticipated that free selling and the holding of such large stocks would result in much lower prices, and to that extent fears on this score had not been justified. These prices would result in a loss on most of the stocks now held in Chile, and would not allow of any oficinas, except the cheapest producers, manufacturing at a profit. It was hoped that some relief would be obtained from the heavy export duty of £2 12s. 6d. per ton, but the Chilean Government have now stated that there would be no reduction before July, 1928. Meantime, the export duty on iodine had recently been increased by 60%.

INTERNATIONAL PAINT AND COMPOSITIONS CO., LTD.

At the nineteenth ordinary general meeting, held on March 16, Sir William Maxwell, K.B.E. (chairman), said that the year under review had been a most difficult one for all industries in this country. The coal strike had deprived the company of some of the raw materials essential to its business, thereby adding to the cost and the difficulties of production. Despite these difficulties, the results of the year's work were not unsatisfactory. The net profit was £64,871, compared with £67,496 in 1925, and a final dividend was declared of 3%, less tax, on the preference shares, making 6%, and a final dividend of 4%, less tax, on the ordinary shares, making 7% for the year. Reserve received £25,000, and £15,105 was carried forward. For many years the company had made at Felling-on-Tyne steel drums and containers for their own paints and compositions, and had found a ready market for their surplus production. It was now decided to transfer part of this business to the south. The new factory at Grays, on the Thames, had been in operation since November last, and, despite many difficulties, had given an output of 155,274 containers of large type. The company had made a good start in 1927, and there were promising signs in the shipping world.

JURGENS, LTD.

The net profit for 1926 amounted to £322,678, against £302,702 for 1925, and with £108,871 brought in there is an available total of £431,549. A dividend has been recommended on the ordinary shares of 5%, tax free, leaving £131,549 to be carried forward.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton. f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit. 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammiac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.

Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.
 Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubbron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16½ Tw. per gal.
 Wood Creosote.—1s. 9d. per lb., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8½d.—9d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 8d.—2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol.—1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 10d.—1s. 11d. per gal. Solvent 95/160, 1s. 6d.—1s. 7d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals, £11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4).—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis. d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.

Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.
 Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—Cryst. £40—£43 per ton. Powder £44—£47 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 6½d.—1s. 7½d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 3½d.—1s. 5d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate. 3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24—£27 per ton, Powder £26—£29

per ton, according to quantity, carr. paid any station in Great Britain in ton lots.
 Bromides.—Ammonium.—2s. 3d.—2s. 4d. per lb. Potassium.—1s. 10d.—1s. 11d. per lb. Sodium.—2s. 1d.—2s. 2d. per lb. All spot.
 Calcium Lactate.—1s. 2½d.—1s. 4½d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ether meth.—1s. 1d.—1s. 1½d., per lb., according to sp. gr. and quantity. Ether purif. (Aether B.P. 1914).—2s. 3d.—2s. 4d., according to quantity.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiaccol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ½ lb., 9s. 6d. per doz.; ¼ lb., 6s. 6d. per doz.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—4d. per lb., 22s. per cwt., according to quantity.
 Magnesium Carbonate.—Light Commercial £31 per ton net.
 Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 10s. 6d.—12s. per lb., according to quantity; Liquid (95%), 12s. per lb.; Detached cryst., 14s. 6d. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig. 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonol.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin.—3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar 100s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17s. 2d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 6s. per ton, d/d. consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.
Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
Sulphonol.—7s. 6d. per lb.
Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.
Thymol, Puriss.—10s. 3d.—10s. 9d. per lb., according to quantity. Natural.—12s. 6d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
Anubine (*ex Anethole*).—10s. 6d. per lb.
Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.
Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.
Cinnamic Aldehyde.—Natural, 17s. per lb.
Coumarin.—10s. 6d. per lb.
Citronellol.—14s. 6d. per lb.
Citral.—8s. 9d. per lb.
Ethyl Cinnamate.—10s. per lb.
Ethyl Phthalate.—2s. 9d. per lb.
Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.
Methyl Anthranilate.—8s. 6d. per lb.
Methyl Benzoate.—4s. 6d. per lb.
Musk Ketone.—35s. per lb.
Musk Xylol.—8s. 6d. per lb.
Nerolin.—3s. 9d. per lb.
Phenyl Ethyl Acetate.—12s. per lb.
Phenyl Ethyl Alcohol.—10s. 6d. per lb.
Rhodinol.—32s. 6d. per lb. Safrinol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—14s. 9d. per lb.
Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 2s. 1d. per lb., Ceylon, Pure, 1s. 10d. per lb. Clove, pure—6s. per lb.
Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 3d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 6d. per lb. Peppermint.—Wayne County, 17s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than July 30th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on June 16th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Bishop, Elsmore, and Holford. Apparatus for treatment of sludge. 14,357. May 27.
Hammond and Shackleton. Heat-treatment of liquids and solids. 13,831. May 23.

Heylandt. Separating and liquefying gaseous mixtures. 13,823. May 23. (U.S., 24.5.26.)
I.-G. Farbenind. Carrying out exothermic reactions. 14,101. May 25. (Ger., 10.7.26.)
Imray (Monsanto Chem. Works). Catalytic process for oxidation. 14,090. May 25.
Kehren. Furnaces. 14,347. May 27. (Ger., 30.6.26.)
Kilmarnock Engineering Co., Ltd., and Shaw. Drying-apparatus. 14,190. May 26.
Paterson. Filtering-apparatus. 14,071. May 25.
Raw. Separation of solid materials of different sp. gr. 14,192. May 26.
Silica Gel Corp. Separation of gases etc. 14,095. May 25. (U.S., 24.6.26.)
Sturgeon. Grinding machinery. 14,238. May 27.
Williamson. Drying-apparatus. 14,190. May 26.

I.—Complete Specifications

1888 (1926). Chur. Separation of a mixture of liquids having different boiling-points. (271.130.)
12,131 (1926). Löffler. Apparatus for heating fluids. (252.163.)

Production of hydrocarbons from mineral oils etc. 14,179. May 26. (Ger., 11.6.26.)
Koppers Co. Coking-retort ovens. 14,325. May 27. (U.S., 27.11.26.)
Coke-oven batteries. 14,359. May 27. (U.S., 12.4.27.)
Laing and Nielsen. Manufacture of water-gas. 14,430. May 28.
Novelli. Process of combustion for coal, lignite, etc. 14,147. May 26. (Italy, 27.5.26.)
Simon Extracting Machine Syndicate, Ltd., and Simon. Refining oils. 14,294. May 27.
Troeknungs-, Verschmelungs- und Vergasungs-Ges., and Bartling. Recovery of dry distillation substances from hot oven gases. 14,226. May 26.
Wetherbee. Production of artificial fuel. 13,986. May 24. (U.S., 10.7.26.)

II.—Complete Specifications

5137 (1926). Lymn. Producing high-grade combustible gases from bituminous fuel. (271.173.)
5219 (1926). Potts (Mineral A.-G. Brig.). Production of bitumen or oil emulsions. (271.177.)
15,117 (1926). Harrison and Drake. Apparatus for receiving coke discharged from retorts used in the manufacture of gas. (271.260.)
27,123 (1926). Koppers Coke Oven Co., Ltd. (Koppers). Method and apparatus for cooling coke. (271.327.)
*12,402 (1927). I.-G. Farbenind. Transforming hydrocarbons of high b.p. into those of low b.p. (271.451.)

*12,403 (1927). I.-G. Farbenind. Manufacture of hydrocarbons. (271,452.)

*13,267 (1927). Feige. Production and conversion of oils. (271,473.)

*13,389 (1927). Battig. Producing hydrogen by decomposing saturated or unsaturated hydrocarbons or gaseous mixtures containing the same. (271,483.)

*13,528 (1927). Battig. Producing hydrogen in the fractionation of coke furnace gases. (271,491.)

IV.—Applications

British Dyestuffs Corp., Davidson, and Shepherdson. Manufacture of vat dyestuffs. 14,217. May 26.

British Dyestuffs Corp., and Mendoza. Manufacture of dyes. 14,352. May 27.

Holliday & Co., and Shaw. Dyestuffs. 14,393. May 28.

I.-G. Farbenind. Manufacture of α -anthraquinonyl ketones. 14,091. May 25. (Ger., 25.5.26.)

Imray (I.-G. Farbenind.). Manufacture of black copying colours. 13,965. May 24.

Johnson (I.-G. Farbenind.). Production of amines for the hydroaromatic-aliphatic series. * 13,822. May 23.

Soc. Chem. Ind. in Basle. Manufacture of dyestuffs. 14,333. May 27. (Switz., 29.5.26.)

IV.—Complete Specifications

4565 (1926). Brit. Synthetics, Ltd., and Higgins. Manufacture of intermediate products for the preparation of azo dyestuffs. (271,146.)

5758 (1926). Brit. Dyestuffs Corp., Rogers, Stubbs, and Emerson. Manufacture of halogenated indanthrones. (271,181.)

6245 (1926). I.-G. Farbenind. See XV.

8311 (1926). I.-G. Farbenind. Manufacture of aralkylamines and their derivatives and intermediate products. (249,883.)

16,671 (1926). I.-G. Farbenind. Manufacture of vat dyestuffs containing nitrogen. (254,742.)

V.—Applications

Brandwood. Production of viscose. 14,234. May 27.

British Celanese, Ltd., Bower, Dreyfus, Kinsella, and Taylor. Production of artificial filaments etc. 13,785. May 23.

Courtaulds, Ltd., Hazeley, Morton, and Topham. Manufacture of artificial threads etc. 13,819. May 23.

Du Pont Rayon Co., Inc. Production of artificial horsehair, films, etc. 13,805. May 23. (U.S., 21.5.26.) Manufacture of viscose. 13,806. May 23. (U.S., 12.6.26.)

Hovey. Making paper pulp. 13,789. May 23.

I.-G. Farbenind. Disintegrating vegetable fibre bundles. 13,842. May 23. (Ger., 21.5.26.) 14,178. See VI.

V.—Complete Specifications

11,507—8 (1927). I.-G. Farbenind. Fulling of animal fibres. (270,333—4.)

*3917 (1927). Soc. Brevets Étrangers Lefranc & Cie. Hydrolysis of cellulose substances. (271,410.)

*10,341 (1927). British Celanese. Products obtained with cellulose derivatives, and methods of reproducing them. (271,425.)

*13,805 (1927). Du Pont Rayon Co., Inc. Manufacture of rayon artificial horsehair, films and the like. (271,517.)

VI.—Applications

I.-G. Farbenind. Dyeing acetate silk. 13,966. May 24. (Ger., 24.7.26.) Dyeing cellulose esters etc. 14,178. May 26. (Ger., 8.6.26.)

Soc. Chem. Ind. in Basle. Producing fast tints on vegetable fibres etc. 14,332. May 27. (Switz., 27.5.26.)

VI.—Complete Specifications

28,281 (1925). Clavel. Dyeing, printing, or stencilling of products containing cellulose acetate. (270,987.)

VII.—Applications

Frischer. Producing volatile acids. 14,056. May 25. (Ger., 27.5.26.)

Grenier. Catalyser for preparation of hydrogen etc. 13,837. May 23. (Belg., 22.5.26.)

Johnson (I.-G. Farbenind.). Manufacture of carbon disulphide. 14,180. May 26.

Ormandy. Manufacture of nitric acid. 14,108. May 25. Titanium Alloy Manuf. Co. Obtaining zirconium compounds. 13,808. May 23. (U.S., 27.5.26.)

VII.—Complete Specifications

11,769 (1926). Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler, and Kerschbaum. Stabilising hydrocyanic acid. (271,236.)

12,979 (1926). Orkla Grube-Akt. Treatment of solutions containing zinc chloride. (252,388.)

*11,837 (1927). Meyerhofer. Producing soluble hydrates. (271,440.)

*13,388 (1927). Müller. Production of synthetic ammonia. (271,482.)

*13,389 (1927). Battig. See II.

*13,528 (1927). Battig. See II.

*13,741 (1927). Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler. See XXIII.

VIII.—Applications

Allen and Deering. Transfers for decoration of pottery etc. 14,065. May 25.

Matthews. Decoration of porcelain etc. 14,064. May 25.

VIII.—Complete Specifications

4276 (1926). Sidler. Manufacture of glass. (271,136.)

24,524 (1926). Riera. Manufacture of synthetic aquamarine stones. (271,316.)

*13,596 (1927). British Thomson-Houston Co., Ltd. Heat-resistant compounds. (271,503.)

IX.—Applications

Anderson. 14,360. See XIII.

Dickinson. Rotary cement kilns for aluminous cement manufacture. 13,901. May 24.

Thompson. Concrete. 13,961. May 24. (Australia, 12.6.26.)

IX.—Complete Specifications

7367 (1926). Anderson. Preserving stone, brick, etc. (271,203.)

25,302 (1926). Lindman. Producing porous concrete. (262,394.)

X.—Applications

Berzelius Metallhütten Ges. 13,829. See XI.

Billington. Copper alloys. 14,067. May 25.

Bischitzky. Recovery of metals from alloys etc. 13,786. May 23.

Krupp Grusonwerk A.-G. Working up ores etc. 13,943. May 24.

Lange. Aluminothermal pressure welding. 14,433. May 28.

Marguerat (Ringsdorf-Werke A.-G.). Drying and extracting gases from metallic powders. 14,422. May 28.

Patten. Chromium plating. 14,364. May 27. (U.S., 20.10.26.)

Soc. Gén. Métallurgique de Hoboken. Treatment of zinc ores. 14,362. May 27. (Fr., 30.12.26.) Roasting zinc sulphide ores. 13,863. May 23. (Fr., 27.5.26.)

X.—Complete Specifications

17,905 (1926). Wade (Internat. Nickel Co.). Treatment of mattes containing nickel. (271,282.)

19,727 (1926). Schmidt. Splitting up metal alloys into their component crystals by centrifuging. (271,293.)

20,776 (1926). Metals Production Corp. Treatment of iron and steel articles. (264,788.)

21,319 (1926). Martyn. *See* I.
8900 (1927). Oalberger. Copper-tin-nickel alloy (268,798.)

*12,454 (1927). Siemens & Halske A.-G. Copper-beryllium alloys and their treatment. (271,454.)

XI.—Applications

Allen Electrolytic Cell Corp. Electrolytic cells. 14,429. May 28. (U.S., 3.7.26.)

Berzelius Metallhütten Ges. Electrolytically refining metals etc. 13,829. May 23. (Ger., 21.5.26.)

British Thomson-Houston Co. Electric furnaces. 13,781. May 23. (U.S., 5.6.26.)

Internat. Copperlad Co. Apparatus for electrodeposition. 14,372. May 28. (U.S., 19.8.26.)

Patten. 14,364. *See* X.

Siemens Bros. & Co., Ltd., and Riber. Electric batteries. 14,187. May 26.

Trotter. Electric accumulators etc. 13,929—30. May 24.

Van Raden & Co., and Starley. Electrical storage batteries. 13,914. May 24.

Westfelt. Producing insulating material. 14,424. May 28.

Wolff. Electric cells. 13,836. May 23.

XI.—Complete Specifications

30,791 (1926). Siemens-Elektrowarme-Ges. Electric bright-annealing furnaces. (262,468.)

*13,544 (1927). Comp. Franç. pour L'Exploit. des Proc. Thomson-Houston. Manufacture of electric dry cells and dry batteries. (271,496.)

XII.—Application

Armstrong (Kokatnur). Anhydrous soap gels. 13,740. May 23.

XIII.—Application

Anderson. Coating for metal, wood, etc. 14,360. May 27.

XIII.—Complete Specifications

4632 (1926). Millar. Water paint or distemper. (271,149.)

15,676 (1926). Steppes and Traun. Manufacture of transparent and colourless condensation products of carbamide and solid polymerides of formaldehyde. (271,264.)

16,335 (1926). Dyk. Polymerised vinyl chloride modification and process of utilising the same. (255,837.)

XIV.—Complete Specifications

5195 (1926). Anode Rubber Co., Ltd. Production of rubber goods directly from latex. (252,673.)

27,239 (1926). Yates. Manufacture of a jelutong product. (271,329.)

XV.—Applications

Botson. Treatment of hides and skins. 13,945. May 24. (Belg., 2.6.26.)

German and Paiseau. Treatment of skins. 14,339. May 27. (Fr., 3.6.26.)

Guillomin. Impermeabilising leather etc. 14,198. May 26. (Fr., 2.6.26.)

Johnson (I.-G. Farbenind.). Artificial masses containing casein. 13,821. May 23.

XV.—Complete Specifications

6245 (1926). I.-G. Farbenind. Manufacture of coloured dressings for leathers. (248,767.)

9777 (1926). British Glues & Chemicals, Ltd., Duncalfe, and Cotes. Manufacture of artificial horn. (271,221.)

XVI.—Complete Specification

*13,370 (1927). I.-G. Farbenind. Fungicide. (271,480.)

XVII.—Applications

Chem. Fabr. vorm.-Schering. Manufacture of lævulose from inulin. 13,866. May 23. (Ger., 15.6.26.)

Gaspary. Manufacture of sugar. 13,763. May 23.

Sugar Beet & Crop Driers, Melrose, and Stead. Production of sugar from dried beet. 13,970. May 24.

XVIII.—Applications

Levin. Yeast preparation. 14,075. May 25. (Sweden, 26.5.26.)

MacLean. 13,778. *See* XX.

XVIII.—Complete Specifications

5191 (1926). Loon. Fermentation processes. (248,373.)

28,545 (1926). Jansen. Fermentation processes for the production of alcohol. (271,336.)

XIX.—Applications

Egg Patents, Ltd. (Milroy). Preserving eggs etc. 14,057. May 25.

Penfold. Preserving eggs. 13,856. May 23.

Sherman. Preservation of food. 13,964. May 24.

XIX.—Complete Specifications

4440 (1926). Scott & Son (London), and Riley. Drying chambers for vegetables etc. (271,143.)

5559 (1926). Potts (Gruyère Usines Laitières Soc. Anon.). Production of milk chocolate. (248,391.)

XX.—Applications

Comp. de Béthune. Preparation of ethylsulphuric acid. 14,211. May 26. (Fr., 24.6.26.)

Johnson (I.-G. Farbenind.). 13,822. *See* IV.

Kirkwood and Raymond. Production of eugenol etc. 13,963. May 24.

Ruzicki. Production of acetic anhydride. 14,328. May 27.

Stiepel. Manufacture of hydroxy-acids. 14,337. May 27. (Ger., 4.6.26.)

MacLean. Medicinal products obtained from yeast. 13,778. May 23.

Bruck. Medicinal preparations for diabetes etc. 13,850. May 23.

Carmael (I.-G. Farbenind.). N-alkylation with amino-alkyl halides. 13,952. May 24. Manufacture of substituted 4 : 4'-dihydroxybis-acylamino-arsenobenzenes. 14,343. May 27.

XX.—Complete Specifications

5047 (1926). Johnson (I.-G. Farbenind.). Manufacture of glycol ethers. (271,169.)

7136 (1926). Wyld. Manufacture of organic arsonic compounds. (249,515.)

9040 (1926). I.-G. Farbenind. Manufacture of aromatic aldehydes. (250,955.)

23,790 (1926). I.-G. Farbenind. Manufacture of esters. (259,204.)

27,588 (1926). Établ. Poulenc Frères. Preparation of a concentrated and stable solution of 3-acetamido-4-hydroxy-phenylarsinic acid from its ammoniacal salt. (264,797.)

28,111 (1926). Andersen, Liesbye, and Weitzmann. Production of complex aurothiosulphate compounds. (261,048.)

31,430 (1926). Hoffmann-La Roche & Co. A.-G. Manufacture of ureides of dialkyl- or arylalkyl-acetic acids. (264,804.)

*13,124 (1927). I.-G. Farbenind. Manufacture of acid derivatives of the 4-hydroxy-2 : 6-dimethylpiperidine-3-carboxylic esters. (271,467.)

*13,531 (1927). Chem. Fabr. vorm. Schering. Obtaining germ gland hormones from vegetable organisms. (271,492.)

XXI.—Applications

I.-G. Farbenind. Producing direct positives by reversal. 14,092. May 25. (Ger., 24.12.26.)

Joseph. Photographic developing apparatus. 14,367. May 27.

Martinez. Colour photography. 13,911. May 24.

XXI.—Complete Specifications

931 (1926). White (Rainbow Photo Reproductions, Inc.). Photoprinting. (271,127.)

16,680 (1926). Berthon. Manufacture of films for colour cinematography. (264,123.)

*13,274 (1927). I.-G. Farbenind. Photographic emulsions. (271,475.)

*13,631 (1927). Bernet. Producing light-sensitive films. (271,507.)

XXIII.—Applications

Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler. Fumigating etc. mixtures. 13,741. May 23. (Ger., 22.5.26.)

Prüss. Sewage treatment. 13,772. May 23.

Techno-Chemical Laboratories, Ltd., Boberg, and Testrup. Treatment of sewage. 14,346. May 27.

XXIII.—Complete Specification

*13,741 (1927). Deutsche Gold- u. Silber-Scheideanstalt vorm. Roessler. Production of fumigating mixtures containing hydrocyanic acid. (271,514.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Brass and copper ware, cut-glassware (554). *British India*: Crockery, glassware, stationery (556); Steelwork (The Director-General, India Store Department, Belvedere Road, Lambeth, S.E.1). *Canada*: Fireproof roofing, tiles (559). *Chile*: Black galvanised piping and fittings, leather beltings (584). *Germany*: Oilseeds (566), Steel tubes, brass and copper plates (567), Leather (568); Machinery, metals, chemicals (570). *Greece*: Sugar (571). *Hungary*: Tin foil, cocoa butter substitute (574). *Japan*: Leather (580). *New Zealand*: Tinsplate, perfumery (560). *Peru*: Iron (585). *Portugal*: Tinsplate (575). *South Africa*: Linseed oil (B.X. 3556). *Syria*: Metals, paper, cardboard (578); Paper (579).

Drugs and Merchandise Marks Act

The Board of Trade give notice of its intention to exempt uncompound drugs from the requirement that imported goods bearing a British name or trade mark must also bear an indication of origin. This exemption will not extend to proprietary articles, or to articles sold in their original packing. Any communication on the subject should be addressed to the Secretary, Board of Trade, Great George Street, Westminster, S.W.1, before June 9.

New Dyestuffs

The British Dyestuffs Corporation, Ltd., have recently issued two new pattern cards describing additions to their range of direct cotton colours, viz., Chlorazol Orange PO and Chlorazol Fast Helio 2 RK. Chlorazol Orange PO is applicable to all forms of cotton material, giving bright yellowish-orange shades of good fastness to light, hot-pressing and washing. It possesses good solubility and affinity and excellent level dyeing properties. It is also suitable for dyeing union material of cotton and wool and of silk and cotton. On viscose artificial silk it gives fairly even shades on material of irregular quality. It is suitable for dyeing silk, and also gives shades of good fastness to milling on wool, and in addition can be used for dyeing jute, tagal, and wood chip. Chlorazol Fast Helio 2 RK is a bright reddish violet, and is particularly interesting owing to its very good fastness to light coupled with excellent solubility and levelling power. It is

specially suitable for dyeing cotton yarn and pieces, and works well in circulating machines, although it is equally suitable for all other types of cotton materials. The dyer of artificial silks will find this colour of interest owing to its property of giving even shades on viscose material of irregular quality; it is also suitable for dyeing cotton-acetate silk mixtures, the artificial silk being unstained in pale and medium shades; also for dyeing silk, jute, and tagal, whilst the union dyer will find it of service for covering the cotton at low temperatures in wool-cotton mixtures.

A further B.D.C. pattern card describes a new union colour "Black D," which gives solid black shades on cotton, silk and viscose materials. Union Black D has been received with approval by many garment dyers, to whom the colour should be of great value.

In a further pattern card attention is drawn to the latest addition to the B.D.C. range of colours for cellulose-acetate silk, "Duranol Brilliant Blue G Paste." This colour gives very bright blue shades of excellent fastness to light and washing, and, owing to its non-staining property, is particularly valuable for the dyeing of cotton and cellulose-acetate mixtures. It can be used in combination with their other Duranol and Ionamine colours.

A new addition to the B.D.C. chrome colours is "Solochrome Black P.V.," which has excellent fastness to potting, being the fastest potting chrome black on the market. Dyers of loose wool and slubbing will find it indispensable because of its very good general fastness. Owing to its excellent solubility, it is suitable for dyeing in all types of machines.

News from Advertisements

The Newcastle and Gateshead Gas Company invite applications for the post of chief chemist (p. viii).

The City of Cardiff Education Committee make an amended announcement regarding the vacancy for the Assistant Lectureship in Pharmaceutical Chemistry (p. viii).

The City Council and University of Manchester invite applications for the Professorship of Technological Chemistry (p. viii).

An agency in Hungary for chemical products is required (p. viii).

A chemist wishes to obtain a partnership in a consulting practice.

EDITORIAL

The Messel Memorial Contributions

THE generosity of the late Dr. R. Messel endowed the Society with a sum, which, including undistributed income, now amounts to £25,000, and the income is available for most of the wishes of the Society. The Council recently decided to ask a small number of distinguished men to write articles on topics of interest to the chemical industry as Messel Memorial Contributions, and to offer an honorarium from the income of the Messel Fund. It is hoped that five or six of such articles may be published every year, and we think that the project will be very satisfactory to our readers. The articles will be important ones, contributed by men of reputation, and they will appear in CHEMISTRY AND INDUSTRY. Hitherto most of the really important contributions to our knowledge have appeared in *Transactions*; this anomaly has been convenient, but the effect of the new departure will be to maintain a more even level of excellence in both these two branches of our JOURNAL. We publish this week the first of the Messel Memorial Contributions, an article on the Production of Clean Coal, by our past President, Professor Louis, whose experience in chemistry, in engineering and in mining, especially coal mining, has been very exceptional. We hope that this will be followed by a Messel Memorial Contribution by Professor Sabatier on Catalysis, and that the other articles will be by writers who are equally well-known. The production of clean coal has become a matter of prime consequence to the community, and lack of attention to the necessity and the cost of this production has been one of the obstacles which have hindered the development of low-temperature carbonisation. As Professor Louis points out, we can hardly expect or desire to remove all the ash from coal before it is burned, but we can remove so much extraneous inorganic matter as to leave a coal the improvement in which outweighs the cost of the cleaning. We suppose that the experience of the next six or twelve months will throw a great deal of light on the commercial possibilities of low-temperature carbonisation, and it seems hardly overstating the case if we say that there is a reasonable

hope that this development may prove to be commercially profitable. Many other developments in our fuel industry are the objects of investigation, and the production of clean coal is one factor in many of these. We are able to congratulate Professor Louis and our readers on the appearance of this important paper, the first, we trust, of a long and honourable list of such contributions.

Our Buyer's Guide

We think we are right in stating that the chemical industry is the sixth largest in this country, and that it is steadily growing in numbers and importance. Partly because it is a new industry and the profession of chemist is a new one, the periodical literature dealing with the chemical industry is very much smaller than the industry deserves. Twenty years ago two comparatively small journals sufficed for what was then a small industry; to what extent is the periodical literature dealing with the chemical industry now adequate to the needs of the industry and the profession? How does the industry compare in this respect with agriculture, engineering, brewing, chicken-farming, shipping and so on? How does our profession compare in this respect with medicine and the law? We claim that this JOURNAL caters extremely well in its abstracts, transactions, articles and news, for the chemists who are engaged in industry, and is necessary to many other chemists. It is, moreover, becoming of increasing value to many who are engaged in the chemical industry, but can hardly claim that coveted, and perhaps almost over-priced, title of chemist. One proof of the increasing number of such readers is the growth of our buyer's guide. During the last few months this has doubled in volume, but in our opinion it should grow much more. The chemists know, by tradition, where to buy nitric acid, copper sulphate, beakers and spectrometers. But many buyers are not chemists, and we think that we members of the Society of Chemical Industry should have in front of us week by week, in our own JOURNAL, a far more complete epitome of our great industry. It should be so complete as to be of great value to all in the industry. We cannot say yet

that it is so complete ; it is more complete than it was ; it is more useful than it was ; it is slowly growing, and it should continue to grow. Let us as members of the Society take a broad and long view of the position of this JOURNAL in relation to the industry ; let us consider what we ought to attain to, what we deserve to have ten years hence, and what steps we ought to take to obtain our hearts' desire. These problems can only be faced piecemeal and gradually ; on the other hand those who face them in due course will be building up for themselves a secure position in the future. Our JOURNAL has during the last generation increased from a monthly journal to a weekly one ; since it became a weekly one it has been converted from a liability into an asset, looking at it solely from a pecuniary point of view ; it is destined, if we members of the Society of Chemical Industry have faith, to become larger and even more useful. We speak feelingly on this subject and quite sincerely, bearing in mind the views we held when we were keenly interested in the work of the Society, but had no editorial or other responsibility. We think the next step we should take is for us all to watch with interest every week the slow growth of our buyer's guide : those of us who have any ideas for its improvement should not be shy of giving advice ; a little co-operation and a little patience, a little *esprit-de-corps* and a little thought will enable us to have a much bigger and a much better buyer's guide. This will be to our advantage.

The Detection of Poisons

A year or so ago we commented on the fact that the oyster is inadequately obedient to the precepts of our health authorities, as it frequently contains arsenic in excess of that minute quantity permitted by the regulations. The oyster is not the only offender, the mussel, the lobster, the crayfish, and the prawn are sometimes even worse sinners. We were careful neither to hint nor to suggest that our national regulations were unduly strict ; knowledge does not always advance in a straight line, but sometimes in a sinuous curve ; it was from the crest of one wave, representing our then utmost advance that our careful government decided to protect us against the poison arsenic : was it perhaps from the crest of another wave that our careful government decided to protect us against the poisons, benzoic acid and boron ? The crest of the wave is succeeded by the trough, but governments pay little attention to the troughs ; they wait until a new crest of suitable eminence arises and then promulgate new ordinances. Mr. King points out a new method of detecting arsenic so delicate as to be almost incredible, and we think a systematic investigation of the fish, and shell-fish, commonly eaten in this country would show unsuspected quantities of arsenic and many other poisons which we refrain from mentioning lest other nutritious and palatable foods become in danger of government interference. Mr. Chaston Chapman, in a paper which recently appeared in the *Analyst*, points out that caramels may contain an acid which is neither benzoic nor salicylic, but may easily be mistaken for these ; also, benzoic acid is a normal constituent of the cranberry and bilberry. He reminds us that heated sugar and all the sweets that our children buy in the shops contain the poison formaldehyde, which is also

prohibited by the regulations ; it seems that nature knows much less about the dangers of preservatives than our government does, and we ought to be very grateful to our government. Edible sea-weeds, according to Mr. Chaston Chapman, contain boron ; this perturbs us not. Few children when on the sea-shore will eat enough sea-weed to contain any great quantity of boron, and the grown-ups who cheerfully, nay even gladly devour the lobster and the scallop, may ignore the much slighter risk from a salad of algæ. Whether we shall ever have any slight misgiving that the new regulations may increase a risk of poisoning by ptomaines or any other products of change or decomposition we do not know. If we were interested in the preservation of potted meats we should try the effect of essence of cranberry, after the removal of its sweetening materials. It seems probable that the use of preservatives in food will become more and more common, and we shall in time become quite accustomed to the flavour of sulphur dioxide, which hitherto we have associated with only the inferior brands of Chablis.

The Propagation of Useful Knowledge

Some of the large companies make a point of circulating to their staff and a few privileged friends at regular intervals information of interest to them. We receive every month from Lloyds Bank a very valuable summary of the world's trade, and other banks make a practice of this nature. The Woodall-Duckham Companies circulate still more frequently a confidential Technical Press Review containing a note, or in some cases almost an abstract, of all the recent publications about fuel. Such journals as CHEMISTRY AND INDUSTRY, *Colliery Engineering*, *Engineering*, the *Gas Age Record* and the *Gas World*, with many other journals, both British and Foreign, are diligently read, and so far as we are able to judge are carefully noted. It must be of considerable advantage to the staffs of such companies to have this information so promptly circulated, and the practice is one which seems to be worthy of extensive adoption. Obviously, the preparation of such a list entails a good deal of time and trouble, but it must be worth a good deal to have a staff kept thoroughly up-to-date in all technical publications. In spite of the numerous publications on industrial chemistry and on the problems of gas, oil, coal and other fuels it takes an unnecessarily long time for the knowledge of recent developments to penetrate the recesses of the human industrial mind. The man who has to decide on the expenditure of money is shy of new methods ; he often prefers that the experiment shall be made by some intimate friend who will run the risk and afterwards divulge in an expansive moment, perhaps after a successful re-double or a run of fluky hazards, what results are really worth noting. This is all very well for the man with the necessary social qualities ; the average man must rely on communications by respectable men in a respectable journal. He is very seldom let down by these, and the expert in his own industry can avoid the few pitfalls which exist. We almost think from the number of extracts from CHEMISTRY AND INDUSTRY that we have seen quoted by the Woodall-Duckham Companies that they and our JOURNAL may almost hope for a reputation for respectability.

THE PRODUCTION OF CLEAN COAL

By **EMERITUS PROFESSOR H. LOUIS, M.A., D.Sc., A.R.S.M.,
M.Inst.C.E., Etc.**

The problem of supplying the industries of the country with coal in the highest possible state of purity is one, the importance of which has only been generally recognised in this country during the last few years. We in this country had the immense advantage that Nature had been generous to us in past geological times, and that our coalfields contained an abundance of thick seams of beautifully clean coal; as long as these were being worked carefully by hand, the coal produced was clean enough for all practical purposes, and needed no further treatment to render it applicable for any industrial purpose. With the gradual exhaustion of some of our thickest and cleanest seams, and the necessity for extracting coal from thinner and inferior seams, with the immense expansion in the quantity of coal produced and, therefore, the need for more intensive methods of mining, in which machine work has largely supplanted hand work, and with, it must unfortunately be admitted, less care and less pride in his work on the part of the miner, the high quality of our coals has gradually declined; whereas at one time we were producing coals of a quality that no other coalfield in the world could equal, to-day we are little, if any better off in this respect than our competitors. Many of these, notably Germany, Belgium and France, and, in more recent years, the United States of America, have found it necessary to employ various mechanical devices for cleaning the naturally inferior coal which their seams yielded. There was no difficulty in devising methods and no lack of appliances, because methods and appliances which had from time immemorial been used in the sister branch of metalliferous mining could be readily adapted to the purposes of coal cleaning, so that the technique of the subject presented no serious difficulties, once the need for the operation was made evident. In this case, as in so many others, a correct statement of the problem was a very long step towards its solution. It is owing, therefore, mainly to our original natural advantages that we in this country have lagged behind the rest of the world in the study of the subject of coal cleaning, but now that the need for it has become apparent here, as it did long ago in other countries, we are energetically making up for lost time, and though we cannot claim to be pioneers, we are readily adopting methods and appliances, introduced in other countries, to our own special needs, for it may be stated at the outset that there is no royal road to the production of clean coal. Each coal must be treated on its merits, and methods thoroughly adapted to dealing with one coal seam may very well prove inefficient with a different one; there is no more any one best method of cleaning coal than there is any one best method of coal mining.

No more striking example of the need for a fuller study of the subject of coal cleaning in this country can be given than the fact recently published in the Press that we have lost certain Scandinavian Railway coal contracts, which were in the habit of coming to this country, to Germany, not, it is stated, on the score of price, but because the German coal is more carefully cleaned than the coal produced in this country.

Perhaps the first question to be answered in any logical discussion of this subject is, "What is meant by clean coal?" Chemists are in the habit of reporting coal analyses upon the dry and ash-free constituents of the coal, and no doubt such a material, if it in fact existed, would represent truly clean coal. There is, however, no such material in Nature, and as we have to do with a natural product, it is useless to set up an ideal standard which, in practice, is impossible of attainment. All coal necessarily contains at least the two impurities which such analytical statements eliminate, namely, inorganic matter and moisture. Coal, as we all know, is the product of partial decay and subsequent chemical changes in vegetable matter, which grew profusely in what appears to have been swampy ground, perhaps in many cases in the deltas of great rivers or along the margins of shallow lakes. All vegetables contain in their substance a certain amount of inorganic matter which is apparently essential to the existence of the plant, and in some cases, at any rate, this assumes considerable proportions. Furthermore, as the coal plants grew on swampy ground, their decaying remains must have been carried down with them a certain proportion of mud, possibly in a colloidal state; some of the inorganic salts dissolved in the water in which the plant remains were submerged must have become concentrated in the vegetable matter, either by adsorption or by evaporation of the water, whilst the plant, both during its lifetime and after its death, is likely to have collected a certain amount of dust brought down by wind or rain. All such inorganic matter may be looked upon as an essential part of the coal substance. When coal is burnt, this inorganic matter, or at any rate a proportion of it, necessarily remains behind in the form of ash, and is usually spoken of as the intrinsic ash of the coal. As a general rule, sufficient distinction is not drawn between the ash left after combustion and the inorganic matter present in the coal itself; if, as is generally the case, the inorganic matter consists of a hydrate such as clay, or of a carbonate such as calcite, or of a sulphide such as iron pyrites, the ash left after combustion has a lower weight than the inorganic matter originally present, and this fact must always be borne in mind in any discussion of the problem. In practice, however, it is impossible to determine inorganic matter in coal save in the form of ash, for the intrinsic inorganic matter, at any rate, cannot be separated from the organic constituents of the coal save by the destruction of the latter.

In addition to the intrinsic inorganic matter, there is in practically every case a certain proportion of extrinsic inorganic matter. This latter is due partly to natural and partly to artificial causes. The extrinsic or accidental impurities may have been introduced into a coal seam either simultaneously with its deposition or formed after the conversion of the vegetable matter into coal is partly or wholly completed. Thus layers of mud and silt or even of fine sand, relatively free from inorganic matter, may have been deposited between the layers of vegetable matter, and now present themselves as shaly or sandy "dirt" partings in the coal seam, ranging from excessively thin layers to beds many inches in thickness. At a later period there must have been introduced the carbonates of lime, magnesia and iron,

which are so frequently found lining the division planes of a coal seam. These are sometimes spoken of as ankerite, but are usually more calcareous than the true mineral ankerite. In the same way thin films of gypsum sometimes occur, and iron pyrites, both cubic and rhombic, is a substance of frequent occurrence in coal seams, being apparently produced by the reduction of solutions of ferrous sulphate circulating through the coaly matter probably during the later stages of its conversion into coal, though it may conceivably in some cases have been produced in quite the early stages of the decay of the vegetable matter. Other accidental impurities are artificially introduced during the operation of coal getting. Generally speaking, coal is mined in the first instance by "kirving" or undercutting a relatively thin slice. As a general rule, when kirving is performed by hand, this is done in the coal substance itself, the thill or floor upon which the coal rests being in many cases too hard to render kirving in it by hand an economic proposition. With the introduction of coal-cutting machinery, however, kirving in the fireclay or shale thill beneath the coal has become quite usual, and this is especially necessary when the coal seam is a thin one, so as to avoid breaking too large a proportion of the total thickness into smalls. Some of the dirt thus cut is very liable to find its way into the coal and thus adds to the extrinsic ash. Again, when the roof is poor, falls are practically inevitable, and even if only small quantities of roof matter fall, quite insufficient to be a source of danger to the miner, these droppings also find their way into the coal and still further add to the accidental impurities. It depends entirely upon the nature and thickness of the dirt partings in a coal seam whether these can be kept out during the operation of mining or whether they are sent to bank with the coal to be subsequently eliminated during the cleaning operation. Until comparatively recently it was difficult, in some cases impossible, to discriminate between intrinsic and extrinsic ash, but within recent years methods for doing this by the application of X-rays have been developed; since the coal substance is organic, composed of elements of relatively low density, coal is highly transparent to X-rays, whilst the various impurities are opaque, and an X-ray photograph of a piece of coal thus shows whether the inorganic constituents are so uniformly disseminated as to be in effect a portion of the coal substance and therefore intrinsic, or whether they occur in compact masses of more or less considerable size, and are therefore extrinsic.

The distinction is one of the utmost importance, because no treatment that can be applied to the coal will remove the intrinsic inorganic impurities, whereas, theoretically at any rate, it is possible to get rid of all such extrinsic matter. As far, therefore, as inorganic matter is concerned, we may define pure coal as coal containing only intrinsic inorganic constituents. Coal is, of course, not a single homogeneous substance, but consists of a number of different constituents mingled in various proportions. The classification of these constituents, originally proposed by Dr. Marie Stopes, is now generally accepted, these constituents being: (1) Durain, the dull, lustreless portion of the coal, (2) vitrain and (3) clarain, the bright shining constituents,

and (4) fusain, the soft, more or less pulverulent portion. It has been found that the proportion of ash varies considerably in these different components: Vitrain and clarain are low in ash, the percentages found by different experimenters ranging from 0.3 to 0.75%; durain generally contains from 4 to 8% of ash, whilst fusain ranges from 10% to 16%. The ash left by vitrain and clarain is largely soluble in water or acids, and apparently represents mainly the inorganic matter which formed an essential portion of the plant structure; the ash left by durain is largely insoluble, and apparently consists to a great extent of the clayey matter introduced in the manner already described; the ash of fusain is often largely calcareous, and is probably due to the infiltration of salts of lime during or after the completion of the conversion of the vegetable matter into coal.

Whilst it is possible to select small specimens of coal containing as little as 1% of ash or exceptionally even less, the intrinsic ash of most coals varies from 2% to 6%, and by our definition this constitutes a practically pure coal, namely, one that contains none except intrinsic inorganic matter.

As regards the other invariably present impurity, namely, water, here, again, it is possible to discriminate between what may be called intrinsic moisture and what may be called adventitious moisture. Under the former head may be included the percentage of moisture adsorbed by coal and retained by it under ordinary atmospheric conditions. Needless to say, the percentage varies with the hygrometric condition of the surrounding air, and probably in most cases ranges from 2% to 4% under ordinary conditions and with coal of ordinary sizes. Coal as it comes from the pit may carry only this amount of adsorbed water, or it may be thoroughly wet, with 10% or even more of water. A good deal of information as to the percentage of water that coal can carry has been accumulated by the investigation of washed coal. Such coal, as it comes from the washery, is, of course, thoroughly wet, and is usually allowed to drain in specially designed drainage hoppers or silos. Under normal conditions such coal generally drains as completely as possible in 48 hrs.; for the next 48 hrs. it may lose a little more water, chiefly by evaporation, and after this the moisture remains practically constant, though it would take a long time for it to get down quite to the intrinsic percentage; after 48 hrs. draining, lump coal, say, above 3 in., usually drains to from 5 to 8% of water, nuts, from 3 in. down to, say, $\frac{3}{4}$ in., may drain to from 8 to 10% of water, and smalls will usually retain over 10 and even up to 30%. These figures are, however, quite approximate, and depend largely upon the character of the coal itself. It is obvious, for instance, that a coal with a large percentage of clarain or vitrain will retain less water than a coal with a large proportion of fusain.

Reference may also be made to certain impurities, which, although they are, in fact, classified as ash, seeing that they are essentially inorganic impurities, nevertheless deserve notice on account of their effect upon the uses to which the coal may be put. One of these is iron pyrites, which occurs in both the cubic and the rhombic form; it may be present either in the form of

concretions or masses of considerable size, or may be very finely disseminated. Its importance is due to the fact that it is one of the principal sources of sulphur in coal, which sulphur may be present in three different forms, namely, as organic sulphur, as a sulphate, generally a sulphate of lime, and as pyrites. Pyrites has a high specific gravity ranging from 4.7 to 5.2, and, therefore, as will be seen in the sequel, it is easily separated from coal when present in a tolerably massive form; it is only the exceedingly finely-divided pyrites or pyrites occurring in the form of excessively thin plates or facings in the joints of the coal that causes serious difficulties in this respect. The presence of sulphur in coal is objectionable for practically all uses to which coal may be put, though it must be admitted that its injurious effect is not very noticeable in house-coal unless the quantity be very great. The presence of sulphur in coal for coke-making is particularly objectionable when the coke is to be employed, as the greater portion of it is, in the manufacture of pig iron, as a considerable proportion of the sulphur present in the coke tends to pass into the iron. In the process of coking, iron pyrites is decomposed, half of the sulphur being evolved and the other half being left behind in the form of ferrous sulphide. When calcium sulphate is present this is probably all reduced to calcium sulphide through the operation of coking. The behaviour of the organic sulphur is by no means thoroughly understood at present, but it would seem tolerably certain that a proportion thereof remains with the coke. Again, sulphur is very objectionable in coal which is used for gas-making, on account of the contamination of the gas with sulphur compounds, both organic compounds and sulphuretted hydrogen being evolved in the process of gas-making. It has been shown experimentally that some of the sulphur present as iron pyrites is evolved in both these forms. It is obvious that in no case can the sulphur which is actually in organic combination with some of the constituents of the coal substance be removed by any process of purification, but the removal, more or less complete, of sulphur present in other forms is possible, and requires special attention in the process of coal cleaning.

The presence of phosphorus is objectionable in the case of coke which is to be used in the manufacture of hæmatite pig iron. Apparently this element always occurs as a phosphate, generally of lime, which is one of the constituents of the ash; the extent of its removal will therefore depend upon the degree to which the ash itself is got rid of, and, in spite of the economic importance which this element may occasionally present, it requires no special attention, since the problem of its removal forms part of the larger problem of the purification of coal from its inorganic impurities.

Another impurity, to which a few words may be devoted, is salt. It is probable that iron pyrites (in many cases) and sulphate of lime are introduced into the coal after the process of the conversion of vegetable matter into coal has been more or less completed; on the other hand it is probable that the salt present has been adsorbed from the water in which the original plants grew or were deposited. Salt is particularly objectionable when coal is to be distilled at high temperatures, whether in the process of coke making or of

gas making; it volatilises at a temperature below that required in either of the above processes, and exerts an injurious effect on the walls of the chamber in which the coal is being treated, more especially perhaps upon coke-oven walls. As is well known, in the presence of moisture salt attacks silica, silicate of soda and hydrochloric acid being formed; it would seem probable that in a reducing atmosphere and in the absence of moisture there would be no action, but it is obvious that water vapour must always be present, and sometimes in considerable quantities, as for example, when wet coal from a washery is being coked. Prof. W. A. Bone* quotes experiments which show clearly that a firebrick is much more strongly attacked by a salty coal when the latter is wet than when it is dry. Some results recently obtained by Mr. C. W. H. Holmes indicate that coal, which contains a good deal of fusain, after crushing showed a much higher percentage of salt in the finer portions than in the coarser portions, and these figures indicate that in all probability it is the fusain that carries the larger proportion of the salt.

This review of the impurities in coal enables an answer to be given to the question, what we mean in practice when we speak of pure coal, and we may set up the definition that pure coal is coal containing only its intrinsic inorganic matter and its intrinsic moisture. There is this difference between these two impurities that the percentage of intrinsic moisture depends not only upon the coal itself, but upon outside conditions, and is therefore variable for one and the same coal, whereas the intrinsic ash of a coal is determined by the character of the coal itself; it varies widely as between the coals from different seams and even as between the coal from different parts of the same seam, but for any particular coal it may be looked upon as a constant. It by no means follows, however, that the object of coal cleaning is to reduce the ash down to intrinsic ash alone; one of the most important problems that present themselves in practice is the question how far any given coal ought to be cleaned so as to give the most economic results. It is in most cases possible to clean a coal so thoroughly that it shall retain only its intrinsic ash, but to do this would often involve the sacrifice of so large a proportion of the valuable coal substance that this is rarely, if ever, attempted in practice. It becomes necessary to set up a standard to which each coal shall be cleaned, that standard being determined by the nearest approximation that can be attained to pure coal as above defined without involving excessive loss of valuable matter. The determination of this standard involves the study of each particular coal, and is perhaps best done by the construction of what is known as a washability curve or Henry curve. A sample of coal to be examined is broken down to a convenient size and a weighed portion placed in a solution of a specific gravity such that a portion of the coal will float and another portion sink; the portion that floats may be further sub-divided by means of solutions of progressively lower specific gravity, and the portion that sinks by solutions of successively higher specific gravity. In this way the coal is fractionated into a number of parts, each having a definite specific gravity; the percentage of each part

* Coal and its Scientific Uses, 1918, p. 48.

is determined by weighing, and the ash in each is then determined by incineration. By setting the percentages of the various fractions off as vertical ordinates, whilst the percentages of ash in each are set off as horizontal abscissæ, a curve is obtained, it is usual to set out also two other curves, derived from the first one, which show the integration of the ash contents in the floats and sinks respectively. From the shape of these curves it is easy to deduce how much valuable coal must necessarily be sacrificed in order to obtain coal in any desired degree of purity. This method is now quite well known, and is becoming very widely employed as a preliminary to the design of a coal-cleaning plant. As far, therefore, as the ash is concerned, the object of coal cleaning is rarely to produce a truly pure coal, but a coal sufficiently pure to satisfy the industrial applications for which it is to be used. Similarly with regard to moisture; within the last few years the dry-cleaning of coal has become an economically practical operation, and although to-day used on a relatively small scale, its employment is rapidly extending, and it will no doubt be generally applied in all cases where the coal itself is not naturally too wet, and where the purposes to which the coal is to be applied demand that it shall be in as dry a state as practicable.

Undoubtedly the removal of the inorganic impurities is the first problem which the coal cleaner has to attack; subsequently he must turn his attention to delivering the coal in the driest possible condition; it is only within the last few years that the latter problem could only be solved with any reasonable measure of success, although its desirability had long been recognised.

The separation of the inorganic impurity or dirt, as it may conveniently be termed, from the coal necessarily depends upon the difference between certain physical properties of the one and of the other, and of these the most important is the difference of density—pure coal, as ordinarily understood, having a specific gravity that does not, as a rule, differ greatly from 1.3, whereas ordinary dirt has a specific gravity of about double that figure. If a given sample of coal consisted of nothing but practically pure coal and pure dirt, the cleaning of the coal would be an easy matter, but, unfortunately, most coals consist of mixtures ranging from pure coal, through coal carrying increasingly larger quantities of dirt, until it becomes what is usually spoken of as bone coal, through carbonaceous shales with continually decreasing proportions of organic matter until pure dirt is reached at the other end of the scale. It is this fact that complicates immensely the problem which the coal cleaner has to solve, and it is on this account that it becomes necessary in the first instance to draw up washability curves, and from these to decide how much of the impure coal shall be taken in with the cleaner coal, and what proportion of bone coal or carbonaceous shale shall be allowed to go off with the dirt. The process of separation, therefore, is not merely designed to separate a light substance from a substance double its own weight, but to separate sharply substances lying on either side of a definitely drawn dividing line, the substances on either side of this line differing but little from each other in density, although all the substances on one side of that line are specifically

lighter than any of the substances lying on the other side thereof.

In order to separate substances of different specific gravity from each other, the separation must take place in a medium which is practically always lighter than the lightest portion of the coal. The only exception to this statement met with in practice is in a recently introduced process known as the Chance sand-flotation process, in which the separating medium consists of water in which sand is maintained in mechanical suspension in such a way as to be equivalent to a liquid of specific gravity higher than the coal though lower than the dirt, so that the former will float whilst the latter sinks in it. The process has been used to some extent, but not sufficiently for a definite opinion to be formed as to its merits. With this one doubtful exception, separation takes place in a lighter medium, which necessarily, however, offers a certain amount of resistance to the movement of any substance through it, the media universally employed being either water or air. The behaviour of bodies falling in such a resisting medium has been elaborately investigated, one of the most recent studies on the subject being that by Dr. Geoffrey Martin.* The falling of a single particle in a medium, as long as that particle exceeds a definite size, appears to follow pretty closely the law first enunciated by Rittinger some seventy years ago, who showed that such a particle tended to move ultimately with a uniform velocity, which can be expressed by the equation

$$V = c \sqrt{D \frac{(S - s)}{s}},$$

where V is the ultimate falling

velocity, D the diameter of the particle, S its specific gravity, s the specific gravity of the medium in which it is allowed to fall, and c is a constant, the value of which depends upon the units in which V and D are expressed, as well as upon the shape of the particle; the above expression, strictly speaking, applies only to spherical particles, but Rittinger has extended its use by postulating a sphere, the mass of which is equal to that of the particle under consideration; necessarily c will vary with the shape of the particle itself. The ultimate falling velocity is only attained at the end of an infinite period, but the increase of velocity from zero is rapid in the first part of the fall, and a practically constant velocity is attained at the end of a relatively short period; furthermore, the expression is important, because it has been found that an ascending current having a velocity exactly equal to the terminal falling velocity, as above calculated, will just keep the particle in suspension, whereas it will fall in a current of lower velocity than this and be carried upward in any current of higher velocity. There is thus indicated a principle by which particles of different specific gravities can readily be separated from each other. Unfortunately, however, Rittinger's principle is frequently applied under conditions which do not warrant its application. Strictly speaking, it should only be applied where a single, roughly equidimensional particle is allowed to fall in a practically infinite volume of medium, and may be considered to be true where single particles are allowed to fall in a body of the medium so large that any upward

* Researches on the Laws of Air Elutriation. The Institution of Chemical Engineers. December, 1926.

current due to the displacement of the medium by the particle is negligible. Such conditions, however, nowhere obtain in practice. In all coal-cleaning appliances the quantity of solid material bears a very considerable proportion to the bulk of the medium enveloping the particles, or, to employ the customary expressions, Rittinger's law only holds true of free-falling particles, whereas in all coal-cleaning appliances a condition of hindered falling prevails. It cannot be said that the laws of hindered falling are as yet properly known. The writer is inclined to think that the ultimate falling velocity attained by a mass of particles falling in a medium under a condition of hindered falling may probably be expressed by equation having somewhat this form:—

$$V = c \sqrt{D \frac{S - s(1 + m)}{s}}$$

in which m is a constant for any given set of conditions, and may be defined as a coefficient of mass concentration, or as a function of the closeness together of the solid particles, or of the ratio which the cross section of the solid particles bears to the cross section of the enveloping fluid medium. In a heap of ordinarily sized coal it is found that the coal occupies about 55% of the total volume, and certain experiments would appear to lead to the inference that for ordinary coal and shale falling in water under normal conditions m probably lies between 0.1 and 0.3. Its value can only be deduced from experimental results; it is, however, clear that its lowest value is 0, which represents the condition of free-

falling, and its highest value is $\frac{S - s}{s}$, which would be the condition when the mass consists wholly of the solid particles.

It must be emphasised, however, that this expression is put forward only tentatively, and that it must not be looked upon as by any means established; although no complete demonstration of its correctness can be given, there would nevertheless appear to be some logical justification for it, because in hindered falling in a medium, upward currents of that medium are set up, and these add to the buoyant effect of the medium in somewhat the same way as though the density of the medium had been increased. It would follow that if two particles of diameter D and D_1 and specific gravities S and S_1 respectively are allowed to fall in a medium of density s , these particles will have an equal ultimate

velocity under free-falling conditions when $\frac{D}{D_1} = \frac{S_1 - s}{S - s}$

and will attain it under hindered falling conditions when $\frac{D}{D_1} = \frac{S_1 - s(1 + m)}{S - s(1 + m)}$. These are, therefore, the rela-

tions that fix the ratio of the sizes of particles of coal and shale of any given specific gravities which allow of the smallest of the shale particles falling faster than the largest of the coal particles, and the ratio is evidently larger in the case of hindered falling than in the case of free-falling particles. This is quite a familiar fact, namely, that when a mass of particles, which would be equal falling under free-falling conditions, are exposed

to the conditions of hindered falling, the smaller and specifically heavier particles fall more rapidly than the larger and specifically lighter ones. This consideration explains why it is that in the majority of appliances in which minerals are separated by their rates of falling through vertical currents of water, it is not necessary to size as closely as the Rittinger formula would indicate, and that the closest sizing appears to be necessary in such appliances as the Draper washer, in which the conditions approximate more nearly to free-falling. In practice the only media that need be considered are water and air, for which s is practically equal to 1 and to 0 respectively; in air, however, m would appear to be comparatively large, so that $s m$ must not be taken as 0, but probably has, on the contrary, a definite value. It is further worth noting that particles falling in air practically never attain the condition of uniform velocity, whilst in the case of particles falling in water that velocity is practically reached when the particles have fallen through a distance given

by the expression $\frac{0.55 D (S - 1)}{S}$ ft., where D is ex-

pressed in inches. It has already been pointed out that the above laws only hold when the falling particle is above a given size, although it cannot yet be stated what that limiting size in fact is. For spherical particles of sand falling in water the limit appears to be about 0.08 inch. For very small particles, the accelerating force of which is so small that the resistance due to viscosity is no longer negligible, the falling velocity is given by an entirely different law, known as Stokes's law, according to which $V = k D^2 (S - 1)$ for particles falling in water, where k is a constant which can be determined as indicated by Stokes. The radius of the particles above which Stokes's law no longer holds good is given by the expres-

sion $\frac{0.00333}{\sqrt{S - 1}}$ inch, so that for coal of density 1.35 the

largest particle that obeys Stokes's law has a radius of 0.0047 inch. Starting with reasonably large particles, as particles progressively smaller are considered, they will reach dimensions when they become too small to obey Rittinger's law; as they become smaller and smaller, they reach a size below which their rate of falling follows Stokes's law; both these laws show a parabolic relation between velocity and diameter and, between the dimensions where these two laws hold good, there is an interval within which a straight line law appears to hold; it can, however, hardly be stated definitely whether this is a true straight line law, whether the exponent of the diameter increases gradually from $\frac{1}{2}$ to 2, or whether the exponent is actually or approximately equal to 1 throughout that interval. There is still room here for much experimental research before the incidence of these laws is fully understood.

It must also be borne in mind that the ultimate falling equation is true only when the régime of equal-falling has been practically established, that is after the particle has fallen through a definite distance as given above; the conditions of falling before the equal-falling condition is attained have never yet been properly

investigated ; it can only be said that of a group of equal-falling particles, the smaller and specifically heavier start more rapidly and fall faster at the outset than do the larger and specifically lighter particles ; in fact, at the very commencement of the period of falling, it is density alone and not the size of the particle which determines its falling velocity. This again accounts for the fact, now beginning to be generally recognised, that close sizing is unnecessary when coal is washed on the familiar bash or jig, perhaps the most widely employed of all coal washing appliances. It was at one time thought that satisfactory washing could not be attained in bashes unless this was preceded by fairly close sizing, but both practice and theory indicate that this view is incorrect, and that relatively quite coarse sizing is all that is needed in order to obtain satisfactory results.

Another principle which is quite widely adopted for coal cleaning purposes is the principle of the trough washer ; generally speaking, every trough washer consists of an inclined trough or its equivalent, in which the material to be cleaned is allowed to flow down in a shallow stream of water. A number of actions take place under these conditions ; in the first place, there is a well-marked tendency to stratification, the shale or dirt tending to form the lowest layers on the trough, whilst the coal occupies the upper layers. This stratification has the effect that the dirt is exposed to greater friction in the course of its passage down the trough, whilst, furthermore, it is acted on by slower moving films of water than is the superimposed stratum of coal. Again, this effect is intensified by the fact that shale tends to break up into relatively thin, flat pieces, whilst coal tends to break into pieces more nearly cubical, and this difference in shape reinforces the effect already explained, the pieces of coal tending to roll down, whilst flat pieces of shale can only slide. The net result is that under such conditions the coal forming the upper layers will travel down the trough more rapidly than the shale which forms the lower layers, and the latter will tend to accumulate on the floor of the trough, especially if this is furnished with dams or weirs behind which it can collect. The earliest trough washers were intermittent in their action, and had, therefore, to be worked in pairs, one being cleaned out whilst the other was in operation, and they also required a good deal of attention and labour. Subsequently, automatic, continuously working, trough washers were introduced, such as the Elliott washer, the Blackett washer, and more recently the Rheolaveur ; the last-named appliance continuously evacuates the dirt and cleaned material against ascending water currents, and, furthermore, differs from the two previously-named appliances in that it is able to produce one or more grades of middlings at the will of the operator.

Another set of appliances, usually spoken of as shaking tables, particularly adapted to small coal, say, under half-an-inch, work on the principle of jerking or throwing the impure coal to be washed in a given direction, whilst a stream of water flows over the appliance usually at right angles to the direction of throw. There are quite a number of different forms of these shaking tables, differing mainly in the mode in which the vibrating action of the table is set up and in the suspension of

the table. All may be described as thoroughly efficient, producing a good separation of clean coal and impurities, and capable of making intermediate classes or middlings as may be required. The production of a class of middlings is a principle which is being adopted with advantage in many coal cleaning appliances, some being so arranged as to return the middlings into the stream of coal to be washed ; this arrangement has the advantage of separating more widely the clean coal and the dirt to be rejected, and thus enabling a more satisfactory separation to be produced, whilst a portion of the middlings may be allowed to go off either into the stream of clean coal or into the rejected dirt according to the market requirements from time to time.

This principle of the vibrating table is, furthermore, of especial importance, because it is the basis of the principle upon which practically all present-day dry-cleaning appliances operate, the essential difference being that the surface of the table is in these appliances composed of a permeable material through which an upward current of air is caused to flow. This upward current of air has the same effect as the current of water in the wet-cleaning appliance, that is to say that it tends to stratify the material, the heavier shale and dirt forming, of course, the bottom layer ; the motion of the table is, therefore, more readily communicated to the material more directly in contact with it, and thus the dirt and the clean coal are caused to move in different directions, more or less at right angles to each other. When the construction of the table is such that anything approaching free-fall is impossible, sizing is not necessarily so close ; in some of the earlier dry-cleaning tables close sizing was indispensable in order to obtain satisfactory results, but this difficulty has been largely overcome in some of the more recent forms.

As already stated, all the successful dry-cleaning plants at present in operation, of which there are quite a considerable number, employ a shaking table in conjunction with an upward air current. There seems to be no good reason why appliances working with puffs of air like the Paddock air-jig and the Krom pneumatic jig, which have been used experimentally in the United States for the dry-dressing of heavier minerals, should not be capable of being so modified as to clean coal successfully ; the fact remains, however, that, up to date, no such appliance has been practically successful.

In connexion with the air-cleaning of coal there is another point of great practical importance to be considered :--

It has already been shown that when particles are below a certain size, they no longer obey the laws of falling upon which all wet-cleaning processes are based, and these fine particles in the ordinary process of coal washing form a slime or sludge, the disposal of which is one of the greatest difficulties of the process. The nature of the sludge requires, in every case, to be carefully investigated. In many coals it naturally consists largely of fusain, which, from its fine, acicular structure, readily breaks up into dust. Since fusain is essentially non-coking, and since the object of coal cleaning is in the majority of cases to produce a clean coal suitable for making a high-class coke, the importance of keeping

out the fusain dust is self-evident. On the other hand, there may be coals in which brittle clarain or vitrain occurs in thin layers, and under such conditions these layers would break up and form a considerable portion of the dust, which, under these circumstances, it would be advantageous to retain with the coal to be coked. In either case, it is becoming more and more clearly recognised that for successful coal washing it is advisable, wherever possible, to eliminate the dust before sending the rest of the coal for treatment. There are conditions when the coal is naturally so wet that the removal of dust without preliminary drying is impossible, and it may be taken as a fairly universal rule that the drying of coal as a preliminary to its treatment is not an economic proposition. With such naturally wet coal, probably the only available method is to wash the coal by one of the wet methods above indicated, and to treat the residual sludge afterwards; occasionally it may be possible to wet-screen the coal first, and to screen off the dust in the form of sludge. In either case this sludge has to be treated, and its method of treatment depends upon its character. If, as is sometimes, though not very often, the case, the fine material is clean enough without further treatment, it may be settled in tanks. In America Dorr settlers are largely and successfully used for this purpose, giving an overflow which is very nearly clear, or at any rate clear enough to go back to the washery, whilst the thickened slime may be turned into the drainage hoppers. If, on the other hand, the fine material contains a large proportion of dirt, as is often the case, especially when the impurities are largely of a clayey nature, probably the best method is to send it to a flotation plant, the principle of which will be presently described. In every case, however, where the coal is not too naturally wet to interfere with successful dry separation of the dust, this should be the first step, whether the coal is afterwards to be treated wet or dry.

Within relatively recent times there have been introduced a number of vibrating screens which are especially well adapted for the efficient screening out of fine material, the Hummer screen being typical of this class. These screens consist of a tightly stretched surface of wire gauze which is kept in rapid vibration by appropriate means, the surface being usually inclined at a pretty steep angle. A screen of this type will sieve out fine particles efficiently, and has at the same time quite a large capacity. Another method, which is also extensively used, consists of sucking or blowing the fine particles out, generally from a falling stream of coal, the fine particles thus extracted being afterwards collected by bag filters, cyclones, or other suitable means.

It has to be admitted that the efficient collecting of this dust is a problem which cannot be said to be completely and satisfactorily solved to-day, though various appliances for the purpose are in practical use. This difficulty of collection certainly constitutes a drawback to this method as compared with the vibrating screen. The method is decidedly an old one, the first patent for thus treating coal going as far back as the year 1849. The advantages of separating the finer particles as a preliminary to cleaning is unquestionable, and with the extension of the modern methods of dust firing, the

product should find a ready, and immediate application. There are cases where the whole of the power required for coal cleaning can be economically generated by means of boilers fired with dust separated from the coal to be treated. It is hardly necessary to emphasise again that this method of utilising the dust is especially suitable when the dust consists wholly or largely of fusain. It will be gathered that the dry-cleaning of coal is especially important because it gets rid of both of the impurities, ash and moisture, which detract from the calorific value of the product. Apart, however, from this consideration, even where for any reason wet methods of cleaning are preferred, as may well be the case when, for example, a costly washery has been installed, or when a relatively wet coal is required for coking, as is the case with certain coals low in volatile matter, the dry separation of the dust before the coal goes to the washing plant constitutes a very important improvement in the entire operation. It must not be forgotten that there are, in this country, not a few cases where the water required for washing has to be paid for, and in any case the circulation of the washery water and the disposal of dirty effluents cost money, and the most obvious means of economising in this respect is by getting rid of the fine sludge-forming particles as a first step.

It need hardly be emphasised that the method of cleaning by all the appliances above considered is based essentially upon the difference between the specific gravities of the coal and the dirt respectively. There are, however, a few processes which depend upon differences in other physical properties of the two materials. One such process is that of flotation.

The principle of flotation is too well known to-day to require description; it depends upon the greater surface tension of a shale-water interface than of a coal-water interface, in consequence of which when two particles of these two substances are introduced into water through which streams of air bubbles ascend, the shale being thoroughly wetted, sinks to the bottom, whilst the particles of coal attach themselves to the air bubbles and are carried upwards into the froth; certain reagents are added, which have the effect of accentuating the difference of surface tension between water and coal and water and shale respectively, and of stabilising the froth. These reagents are inexpensive, substances such as cresol and various cheap oils being used. Various mechanical means are used for producing the flow of air bubbles and for drawing off the froth from the surface of the pulp, and the process acts most satisfactorily, producing a very clean coal and an equally clean reject. The difficulty in the practical application of this process lies in dealing with the froth, which is usually a very tenacious one, and holds a large proportion of water, from which the coal can be separated only with considerable difficulty. Various types of filters and of centrifuges have been tried, but so far without any great success. The method now generally adopted is to mix the froth with the coal washed in some other process, *e.g.*, in bashes, and allowing the mixture to drain in suitable drainage hoppers. Even this method is effective only if care be taken that the froth is thoroughly mixed with the washed coals; if the former is allowed to form distinct layers in the hoppers, it forms a kind of

water-proof sheet, which not only will not drain itself, but greatly hinders the drainage of the other coal. If, however, properly and effectively mixed with the washed coals, it has been found in certain cases that the mixture will drain as effectively, *i.e.*, down to 10% of water, in 36 hrs. as the washed coal without the froth would do in 24 hrs.*

Another interesting process is based on the difference between the frictional resistance experienced by coal and dirt respectively when sliding over any given surface. The most recent application of this process is to be found in the Pardee spiral separator; this consists of an inclined spiral track down which the coal to be treated is allowed to slide. Assume that the material to be treated consists of pieces of coal and of shale, of which the shale, breaking up into flat pieces, moves with more friction than the coal, which tends to break up into more or less cubical blocks. The result will be that the coal will acquire a greater velocity, and if the spiral is suitably arranged the velocity thus acquired may be rendered sufficient to cause the coal to jump over the edge of the spiral track and to fall into a spiral trough running alongside of it. The shale on the other hand will hug the inner edge of the spiral track, and it is possible to so arrange the appliance that material intermediate between the two, such as bone coal, will be delivered separately, thus making three different grades. The appliance was first introduced in the United States for the cleaning of anthracite, which it did very successfully. Many years ago the same principle was utilised for separating anthracite from shale, the appliance then consisting of an inclined shoot down which the material was allowed to slide; at a given distance down there was a gap in the shoot; the more rapidly moving anthracite acquired sufficient velocity to jump over the gap and continue its course down the shoot whilst the slower moving shale dropped into the gap. This form was never used for bituminous coal, but the spiral separator has been thus adapted; it must, however, be emphasised that the appliance is not of universal application, there being cases where the coefficient of friction of the coal and of the shale are so close together that separation on this appliance becomes impossible and examples can even be found where the shale has a lower coefficient of friction than the accompanying coal. The moist or dry condition of the materials also affects the proper working of the appliance. Whilst, therefore, in some cases it has been applied quite successfully, there are others in which it is not applicable, and apparently every proposition for the employment of this separator must be tried out practically before it is possible to state whether or not it will be successful in the given case. In any case the separator does not work successfully on ~~the lower limit~~ the lower limit being usually about $\frac{3}{4}$ -in., and the coal to be treated requires tolerably close sizing. It is quite possible that in the Pardee separator the greater elasticity of coal as compared to shale also comes into play; the spiral track is often intentionally roughened, so that the coal would tend to proceed along it by a kind of bounding or rolling motion, and thus acquires a greater velocity than the sliding shale. Quite recently the principle of difference in elasticity

has been utilised in the Berrisford separator, which causes the impure coal to rebound from an inclined surface, the coal bounding off further than does the shale. This process is quite in the experimental stage, and it is impossible to say whether it will or will not prove to be successful in practice.

It will thus be seen that there are a number of different principles that can be brought into play for the cleaning of coal and that each one of these principles can again be utilised in a number of different appliances. The designer of a coal cleaning plant has, therefore, before him a very wide choice both of principles and of appliances, and whilst it may probably be said that reasonably good technical results can be attained in a variety of different ways, very careful study is required in order to obtain the best economic results in any given case. The one thing to be borne in mind is that every coal cleaning problem is a problem by itself, and that no general solution can be advanced; each proposition must be studied on its merits, and the adoption of any given process or appliance at one pit, merely because it has given good results in another colliery, invites failure unless all the conditions in both cases are fully and carefully investigated. This much, however, can be said without much hesitation: whilst we can no longer in this country depend upon being furnished by nature with the high-class pure coals for which Britain was at one time famous, there is no doubt at all but that pure coal, in the sense in which that term has been used here, can be produced economically by a suitable selection of cleaning appliances, and there is no reason why collieries in this country should put upon the market coal containing either more ash or more water than there is being left in the coals offered to the world's markets by our competitors.

THE INVENTION OF LITHOPONE

By RANSOME W. COOPER

A casual glance at some of the technical books dealing with lithopone reveals an astonishing haziness as to the invention of that highly-useful material. Not only does there appear to be an uncertainty as to the name of the inventor, but also as to the dates involved and even to the first use of the name itself.

For instance, Henry A. Gardner, in his recent book, "Paint Researches and their Practical Application" (p. 39), states: "This pigment (lithopone) was apparently first produced by Orr in 1874." Maximilian Toch, "Chemistry and Technology of Paints," 1926, p. 41, says, "John B. Orr, of England, in 1880 discovered that when (lithopone) is heated to dull redness, suddenly plunged into water, ground in its pulp state, thoroughly washed and dried, its characteristics are totally changed."

Yet J. B. Orr's original specification is dated February 10, 1874, and claims the chilling action as an integral part of the patent.

The date of 1874 is given by Allen Rogers, "Industrial Chemistry," Uebele, "Paint Making and Colour Grinding," J. G. Bearn, "Chemistry of Paints, Pigments and Varnishes," Holley, "Lead and Zinc Pigments," and W. G. Scott, "White Paints and Painting Materials,"

* Rev. Ind. Min., 1926, p. 355.

who all ascribe the invention to J. B. Orr, as does also G. Hurst.

On the other hand, Ullmann's German Encyclopædia (No. 12, p. 245) states that lithopone was first prepared on factory lines in 1853 by De Doudet (misprint for De Douhet),¹ by precipitating zinc sulphate with barium sulphide. He goes on to say that J. B. Orr produced the material in a similar manner, but subjected it to a roasting and cooling process which made it whiter, and more compact, and adds that Boulez introduced the name of lithopone in 1877.

This last statement is incorrect, for we find the name used by V. Leger in the opening words of his patent No. 28,834, May 30, 1871. Moreover, he uses the word as though it were even then of sufficient general employment to require no explanation: "It is noticeable in the manufacture of lithopone, as described in patent No. 26,423 . . ."

It will have been noticed that V. Leger refers to a prior patent dealing with the manufacture of lithopone. This No. 26,423 is that of a patent taken out by himself in Brussels on October 18, 1869. Its method of procedure is so simple, and, moreover, describes so closely the present method of manufacture, that we give it verbatim:—

"En agglomérant intimement quatre parts sulfate de baryte, deux parts sel marin, une part charbon, les exposant ensuite à un feu violent, jusqu'à ce que fusion du sel s'ensuive, j'ai pour résultat de cette opération du sulfure de barium mélangé de chlorure de sodium. De ce produit bien lessivé, décanté clair, j'obtiens le blanc précité en versant dans la moitié de la liqueur une part utile de chlorure de zinc, pour former un précipité de sulfure de zinc et du chlorure de baryum, en liqueur. Je précipite ensuite le chlorure de baryum par du sulfate de zinc, qui fait un précipité de sulfate de baryte, en refaisant du chlorure de zinc. L'autre moitié, du sulfure de baryum étant ajoutée à ces précipités, il devient évident que j'ai par cette triple opération, deux équivalents de sulfure de zinc, contre un équivalent de sulfate de baryte, et pour résidu du chlorure de baryum mélangé de sel marin. Le précipité étant mis sur toile, égoutté, desséché, calciné au rouge cerise, jeté dans l'eau froide pour l'étonner et le rendre opaque; broyé à l'eau en pâte impalpable, lavé et séché, il fait une couleur blanche d'un excellent emploi en peinture."

It will be seen that the whole process, including that of chilling the resulting product, is covered by Leger's patent; but as De Douhet had taken out a Belgian patent on December 25, 1850, covering substantially the same ground, we can only assume that Leger's patent was only a detailed improvement of an existing patent, and not an independent discovery.

With regard to Ullmann's mention of De Douhet,

¹ Lithopone . . . wurde zuerst 1853 von De Doudet (misprint for De Douhet) durch Umsetzung von Zinkvitriol mit Schwefelbarium fabrikmässig hergestellt und als Metallweiss in den Handel gebracht. J. B. Orr in Glasgow (E.P. 517, 1874) gewann die Farbe auf gleiche Weise, unterwarf sie aber einem Glüh- und Abschreckungsprozess, um sie dichter und weisszer zu machen. Diese Operation ist als eine wesentliche Verbesserung aufzufassen. Boulez führte 1877 den Namen Lithopone ein, der sich Anerkennung erlang.

² "On voit que dans la fabrication de la céruse lithopone telle qu'elle est décrite au brevet no. 26,423 . . ."

reference to the latter's patent makes it fairly clear that the invention of lithopone must be laid to his credit. On October 5, 1850, De Douhet³ registered an invention in France (No. 5176), which not only covers what is now known as lithopone, but claims all lithopone-type products resulting from the double decomposition of a soluble metallic sulphate with the sulphides of barium, strontium and calcium. He advises bringing the resulting product to a red heat and plunging into cold water, draining, drying, etc., and finally remarks, "Working, for example, with barium sulphide and zinc sulphate, one obtains an excellent 'céruse'" (white pigment).

There is a suggestion in a previous patent of De Douhet that he was already on the track of his epoch-making discovery. (French Patent, November 6, 1847.)⁴ He brings precipitated barium sulphate to white heat and plunges it into cold water or into a solution of zinc sulphate or lead acetate to render it more opaque. The roasting process will have reduced some of the barium sulphate to the sulphide, and a corresponding interaction with zinc sulphate will have produced a certain amount of lithopone. Hence, one may look upon 1847 as possibly the year when lithopone was first discovered, and certainly 1850 as the year when the first patent for lithopone was taken out, the honour of the invention going to the French chemist, De Douhet.

All the foregoing details are culled from books in the Patent Office, London, and the patents cited may also be referred to there.

3 Brevet d'invention de 15 ans, No. 5176, Oct. 5, 1850.

Il s'agit, dans ce nouveau brevet, de ces doubles fabrications et combinaisons mi-partie alcalines et métalliques, considérées dans leur application exclusive à la peinture à l'huile sans vernis.

Les sulfates qu'il s'agit d'él de désoxyder pour en former des couleurs sont usuellement au nombre de trois: les sulfates de zinc, de cuivre et de fer. La grande disposition qu'ont les sulphydrates alcalins en général, et même les sulfures de chaux préparés par la décoction dans l'eau bouillante du soufre et de la chaux, de précipiter les sulfates métalliques à l'état de sulfures hydratés insolubles, en s'emparant de leur oxygène forme la base de ma découverte.

Si l'on veut avoir la base métallique unie au soufre, mais libre d'autre substance, il faut mélanger ensemble deux solutions: l'une d'un sulfate métallique, l'autre d'un sulphydrate alcalin, dont le sulfate est soluble; tel que celui de soude ou de potasse. Mais, dans l'ordinaire des cas, il est préférable d'obtenir un sulfate métallique hydraté. On le mélange avec un sulfate insoluble, baryte, strontiane, chaux, qui lui donne du corps et le fait foisonner: c'est alors du sulfure de barium, de strontium ou de calcium dont il faut se servir. Le précipité est alors double et coloré, d'après les métaux qui servaient de base.

Pour donner à ces produits toute leur intensité colorante, il est nécessaire de les porter au rouge dans un fourneau et de les éteindre dans l'eau froide; cependant les couleurs à base de cuivre et de fer peuvent couvrir à la rigueur sans cette opération, ainsi que celles obtenues par la double précipitation d'un sulfate métallique avec un polysulfure hydraté de chaux; mais dans ce cas de fabrication, comme il reste dans les liquides une proportion notable d'hyposulfite et de sulfate métallique ou calcaire, il faut, pour les précipiter entièrement, saturer ces liquides avec des sulfures de barium ou de strontium. On les décharge de la sorte de toutes les bases qu'ils tiennent en dissolution. Le dépôt est ensuite décanté, desséché, puis étouffé avec soin; il en résulte, quand on opère, par exemple, avec du sulfure de barium et du sulfate de zinc, une excellente céruse.

Ainsi l'objet du brevet est la confection décrite des couleurs formées par, la double précipitation des sulfures et polysulfures de barium, de strontium de calcium, ainsi que de la baryte, de la strontiane, de la chaux, préparée par voie humide, avec les divers sulfates métalliques solubles.

Certificat d'addition, Aug. 16, 1851.

Et le double précipité thus obtained is mixed with artificial or natural sulphate, brought to a red heat in a furnace and plunged into cold water "les molécules de ces nouveaux composés éprouvent une transformation et, en devenant opaques, constituent des couleurs bonnes à l'employer à l'huile, au vernis et à l'essence."

4 Patent, De Douhet, Nov. 6, 1847.

Quant au sulfate de baryte obtenu en quantité, on l'utilisera, soit en le faisant servir d'excipient à la céruse, après l'avoir préalablement éteint à l'état incandescent dans l'eau froide pure ou chargée de sulfate de zinc ou d'acétate de plomb, pour le rendre plus opaque en l'étonnant . . . Tous ces procédés sont brevetés dans le premier titre.

COL. G. P. POLLITT, D.S.O.

Colonel Pollitt is a man who has both a considerable capacity for work and a quiet determination which is almost unaffected by small obstacles. He quickly and surely makes up his mind as to what he wants, and brushes awkward men or positions firmly aside so that he may pursue his undeviating course; he indulges neither in flattery nor chicane, and he probably learned his ideas of life from watching a tank steadily proceeding through entanglements of wire and brushwood to its chosen terminus. He is courteous without wasting time, but if he is compelled to suffer fools his period of gladness is brief. He is a great asset to British chemical industry.

Born in 1878 at Mellor, near Blackburn, Colonel Pollitt received his early education mainly abroad. His scientific education commenced at Manchester University, where he took the degree of M.Sc.; it was followed by a period of study at the Zurich Polytechnicum. While he was in Switzerland he was awarded the degree of Ph.D. by the University of Basel, for a thesis on the contact process for the manufacture of sulphuric acid. In 1903 he was appointed assistant chemist at Woolwich Arsenal, and in 1904 he became research chemist and manager of the high explosives department of Kynoch, Ltd., at Kynochtown, in Essex. His next appointment was in 1905, as departmental manager for Brunner, Mond & Co., Ltd., where he remained until 1912. In that year Messrs. Brunner, Mond acquired the firms of Messrs. Crosfield and Gossage, and Colonel Pollitt acted as a liaison between them and his firm.

The outbreak of war found him acting as general manager to Hydrogenators, Ltd., and Administrateur Délégué of the Société Anonyme d'Hydrogenation de Marseille, posts which he had occupied since 1913, but in August, 1914, he was serving as despatch rider in the 4th Division in France with the rank of Corporal R.E. From November, 1914, to May, 1915, he served as a second lieutenant in the Intelligence Corps in France, and thereafter until 1917 he held various commands in the Special Brigade R.E., including that of O.C. Trench Mortar Battalion. In 1917 he joined the Infantry and spent six months with the 4th Battalion of the Grenadier Guards, subsequently commanding the 6th and 11th Battalions of the Lancashire Fusiliers. He was wounded four times, and when wounded the last time—in June, 1918—was taken prisoner. For his services he was awarded the D.S.O. and two bars and the 1914 Medal, and was granted the rank of Lieut.-Colonel on demobilisation.

Since the war he has become a director of Brunner, Mond & Co., Ltd., and is the managing director of Synthetic Ammonia & Nitrates, Ltd. He is also a director of The Castner-Kellner Alkali Co., Ltd., The Magadi Soda Co., Messrs. Chance & Hunt, Ltd., The Buxton Lime Firms, Ltd., Messrs. Nitram, Ltd., The United Alkali Co., and The International Combustion Co., Ltd., a member of council and chairman of the Technical Committee, British Sulphate of Ammonia Federation, Ltd., and a director of The Coal Carbonisation Co., Ltd., and Imperial Chemical Industries, Ltd.

We may complete this brief biographical sketch by adding that Colonel Pollitt is a member of the Windham Club and the Royal Thames Yacht Club, and that he is unmarried.

SOCIETY OF CHEMICAL INDUSTRY

OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

EXTENSION OF PERIOD FOR REDUCED RAILWAY FARES

Since the programme for the Annual Meeting was printed, the Railway Companies of Great Britain which agreed to issue tickets at the ordinary single fare and one third for the double journey to persons travelling to Edinburgh to attend the meeting have extended the validity of these tickets, and they will be **available from Saturday, July 2, to Monday, July 11**. These tickets will be obtainable at the time of booking on production of vouchers which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

It is urgently requested that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

PROPOSED EXCURSION TO ST. ANDREWS ON SATURDAY, JULY 9

The train will leave the Waverley Station, Edinburgh, at 9.30 a.m., arriving at St. Andrews at 11.22 a.m.

A visit to the University, including the Chemical Laboratories, will be arranged for the afternoon, and the St. Andrews University Court has kindly offered to entertain the members to tea in the University Buildings.

The return train will leave St. Andrews at 5.35 p.m., arriving in Edinburgh at 7.26 p.m.

Members will also have an opportunity of visiting other places of historic interest in St. Andrews or of playing golf.

CHEMICAL ENGINEERING GROUP

A lunch for Members of the Chemical Engineering Group and their guests is being arranged for Wednesday, July 6, at 12.30 p.m., immediately after the meeting of the Group. The lunch will be held in the University Union, Park Place, Edinburgh. Price of tickets 5s., exclusive of wine and gratuities.

Members of the Society who are not Members of the Group are welcome to attend the lunch.

Charabancs will call at the University Union at 1.55 p.m. for those going to the Gasworks, and at 2.5 p.m. for those proceeding to King's Buildings. Application for tickets should be made **immediately** to the Secretary of the Group, Abbey House, Victoria Street, London, S.W.1. Communications regarding the lunch **after July 1** should be addressed to Dr. W. T. H. Williamson at 13, George Square, Edinburgh.

BUREAU OF CHEMICAL ABSTRACTS

The following are the prices at which copies of the Index to British Chemical Abstracts, 1926, can be purchased:—

By members of the Chemical Society or the Society of Chemical Industry—5s. post free; by subscribers—10s. post free.

MEMBERS ELECTED

June 10, 1927

- Barker, Arthur, 30, New Lane, Moorside, Cleckheaton, Yorks.
 Baxter, Harold R., c/o Messrs. J. & G. Cox, Ltd., Gorgie Mills, Edinburgh. Manager.
 Bowrey, Stanley E., 3, Haydon Street, Minories, London, E.1. Chief Chemist.
 Clemo, George R., Armstrong College, Newcastle-on-Tyne. Professor of Organic Chemistry.
 Fleuret, John B., 47, Walsingham Road, Hove, Sussex. Micro-Analyst.
 Keyes, Alfred W., 14, Wilson Street, Richmond, Auckland, N.Z. Student.
 Prins, Jan A., Bureau voor den industrieelen eigendom, Oostduinlaan 2, The Hague, Holland. Director of the Dutch Patent Office.
 Read, Wilfrid H., Experimental and Research Station, Cheshunt, Herts. Research Chemist.
 Salerni, Edoardo M., 31, Rue Tronchet, Paris. Chemical Engineer.
 Tavrogos, Joseph, c/o West Surrey Central Dairy Co., Ltd., Guildford, Surrey. Chemist.
 Wai, Mao P., National Women's Normal University, Sho Foo Ma Ta Chai, Peking, China. Principal.

BIRMINGHAM AND MIDLAND SECTION

The seventh and last meeting of the session was held at the Birmingham University on April 5, Mr. Collis presiding.

The following lecture on "Ultra-Violet Light" was given by Mr. A. A. King.

More than 250 years ago—in the year of the great fire of London—Newton discovered the spectrum of visible light. In 1777, one hundred and eleven years afterwards, Schegle discovered the action of rays beyond its violet end by means of a sensitive plate. By 1800 Faraday and Boeckmann were exposing substances to violet light, to burning sulphur, to Indian white fire for chemical effects. But it was not till 1912, during the last fifteen years in fact, that Lyman and Milliken and others explored and approximately defined the region of the ultra-violet spectrum. There are yet large gaps, particularly where ultra-violet and X-rays meet.

Until we had means of obtaining arc light our only source of ultra-violet rays was the sun. It is now fifty years since the carbon arc and about twenty-five since the tungsten arc were placed at our service. Still more recently we have been supplied with the mercury vapour arc, and this has now become the source of these rays, of greater or less intensity, both for popular and scientific purposes.

We will first get a precise idea of the geography of the spectrum of the electromagnetic waves from a diagram published by the Royal Society and first exhibited at Wembley. It gives in concise form the relationship and wave lengths of the various regions of radiant energy. From the radium-emitted gamma rays of shortest wave-lengths, one three-hundred-millionth of an inch, to those of 30 miles, beyond the wireless region, given out by our large alternating current machines, there is this simple difference of wave-length. Their frequencies mount from 10^8 to 10^{20} . But their velocity, 186,000 miles per second, is the same. The least explored regions are in the infra-red-Hezian and from X-rays of 100\AA to

ultra-violet rays of 1000\AA . The chart shows that the rays reaching the surface of the earth from the sun lie between $3,000,000\text{\AA}$ in the infra-red and about 3000\AA in the ultra-violet. This second limit is due to the filtering effect of the atmosphere, of ozone and oxides of nitrogen in the outer and of the turbidity and water vapour in the closer atmosphere. As for the ultra-violet rays reaching us, we may consider their approximate limits are 4000\AA , where they meet the visible spectrum and 3000\AA . We may contrast this with the practically effective limits of ultra-violet rays emitted by electrical means of 4000\AA to 1800\AA . Waves of higher frequency are absorbed by the air.

I should like to point out that there is an enormous gap between the longest X-rays which have been produced and the shortest ultra-violet rays which our lamps can yield. Therefore, one could predict with confidence that there is little or no danger of the kind which the early workers with X-rays suffered. Practical experience has fully proved this prediction. While X-rays will penetrate all matter more or less, the shortest ultra-violet rays cannot be made to penetrate anything. The lining of the eye socket is all that needs protection in ordinary work: tinted glass well-fitting goggles are quite sufficient.

As we have stated earlier, the carbon arc was the first artificial source of our rays. This gives a line spectrum fairly evenly dispersed in the ultra-violet, extending from the visible to 2000\AA . The first ultra-violet light treatment for diseases of the human body was practised by Finsen with this arc, which is still much favoured by medical men for certain treatments. It has disadvantages for laboratory and therapeutic purposes: a large current consumption, large emission of heat waves, the difficulty of making it automatic in action, the difficulty of enclosing it completely and avoiding the naked intensely hot flame.

The carbon arc is too well known to need demonstration.

Of the three arcs, carbon, tungsten and mercury, the tungsten arc gives the most evenly distributed line spectrum in our region; within reasonable limits it gives a constant emission of our rays. It is exceedingly valuable for spectrographic work. It, too, has its disadvantages for laboratory and therapeutic work: emission of heat, the necessarily naked flame, fumes of tungstic oxide, the difficulty of totally enclosing it for experiments in fluorescence. From the point of view of cost both carbon and tungsten arcs compare very unfavourably with mercury vapour lamps. We have two general types of mercury vapour lamps, the "vacuum" type where the mercury is enclosed in a hermetically-sealed fused quartz tube and the "atmospheric" where the fused quartz tube is open. In the latter type the dangerous mercury "hammer" is avoided, but it has other advantages. Until quite recently the only method of obtaining cold ultra-violet radiation was by using one of these "vacuum" lamps, in water-cooled jacket.

My earlier experiences in the use of ultra-violet radiation gave me a strong bias in favour of the "atmospheric" type, and it was in my desire to combine the advantages of both types and, as far as possible, to avoid

their disadvantages that I designed the air-cooled medical lamp now on the market. It is far more robust than any vacuum mercury vapour lamp. It can be made to provide a stream of sterilised ozone-charged air for therapeutic practice. The forced draught of air removes the excessive heat, and at the same time has not the absorbent effect upon the ultra-violet rays which accompanies the use of water cooling. A much more intense ultra-violet beam can be produced from the arc tube. This is even more marked in the improved pattern I have constructed, and which I show here for the first time, particularly for all kinds of laboratory work. As you see it combines, in the one instrument, fluorescent cabinet, open lamp for sun baths, medical lamp for applicator work. Experimental cells placed in the rays are kept beautifully cool. I should have liked to carry through some experiments with this lamp here to-night, but the time is too short, and I must content myself with pointing out the convenience of its use for scientific work: the applicator fitting is conveniently replaced by the various forms of quartz vessel.

I have a selection of quartz accessories on this table, including one which has a filter cell combined with a reaction cell. Almost any type of apparatus can be obtained in fused quartz. This substance is remarkably transparent to ultra-violet, as well as to visible and infra-red rays. You will see from the experiment that the ultra-violet rays can be made to describe a complete circle through a quartz rod bent into this shape.

Before I go any further I ought to say a few words about light filters. One of our urgent needs is practical filters by means of which one may isolate any selected region in the ultra-violet spectrum. When a filter is discovered which will pass the shortest ultra-violet rays, a wide field will be open, particularly in medical research. None is at present available, and we are driven, when we would get approximately the result we desire, to compare differences in reaction obtained with filters which still allow visible as well as more or less U.V. rays to pass through them. Perhaps the most useful filter for fluorescence work is Chance Bros.' U.V. glass. This glass, while cutting out all but the extreme red of the visible spectrum (a very faint region between "7000 and 7500 Å"), transmits rays from 4000 Å to 3250 Å. The longest rays in the ultra-violet will also pass through ordinary glass, wherefore fluorescence experiments can be conducted in ordinary glass vessels with this range of radiation. The fluorescence in the glass itself must be allowed for.

We may note in passing that it is physiologically impossible to experience complete darkness in a room into which invisible U.V. rays are emitted. Even though every other material within range is non-fluorescent, the lens of the eye is fluorescent in these rays, and the retina becomes aware of a blue misty illumination. This principle was made use of during the war for invisible light signalling. You will observe here how a beam of U.V.R. which we concentrate in a quartz lens is "picked up" by fluorescent materials.

A much more important application of this effect for the chemist to-day is that of distinguishing by their fluorescence certain imitation gems and precious stones from the pure stones. The method is not confined to

such materials, and it promises important developments. The presence of minute impurity in some substances can be detected by its fluorescence, and afterwards identified by chemical methods.

Even laboratory "distilled" water may profitably be examined in the rays. You will see how certain impurities otherwise unsuspected, show up in this sample, and how it needed a succession of redistillations, culminating in double distillation in platinum vessels, to obtain a practically fluorescence-proof sample of distilled water.

But you will probably be more interested in a super-refinement for testing the presence of arsenic.

Arsenic test.—Some twelve months ago I had recourse to the most refined of the known methods of detecting and estimating minute quantities of arsenic in food substances. Finally, I selected the Gutzeit method, which gives a mercury-arsenic yellow stain, as most suitable for further examination. At attempt to intensify the stain in monochromatic light served its purpose, but it occurred to me to expose the stains to ultra-violet radiation. The work was carried out wholly by the laboratory staff of Messrs. Albright & Wilson, Ltd., of Oldbury. It was discovered that by the method one may estimate quantitatively arsenious oxide of an order of minuteness beyond what has been hitherto possible, with normal Gutzeit, Marsh, or any other method with which I am acquainted. Adsorption of the rays by the mercury-arsenic stain makes this intensely black, so much so that stains which are quite indistinguishable in ordinary light stand out a startling black upon a fluorescent background. We have been able to estimate with certainty as little as 0.0000005 gram As_2O_3 , and to detect even smaller masses. A pleasing by-product of the investigation was the demonstration that it is possible to get materials, such as zinc and sulphuric acid, so pure that an all but perfect blank can be obtained. You see here, in the rays, a series of arsenic stains ranging from 0.000001 gram to 0.0000001 gram As_2O_3 , the last five of which are quite invisible in ordinary light, whether monochromatic or otherwise. The last two slips on the card are the blank and the unused paper, which, as you perceive, itself fluoresces with a gentle bluish light.

Arising from this work here is an interesting example of detection of impurity. You see some quite good samples of crystallised mercuric chloride fluorescing in the rays—some parts of it are a bright pink, while others are very faintly blue. It is noteworthy that a pink fluorescing lump when broken up will yield some pink, some blue fluorescing pieces. This mercuric chloride twice recrystallised in the laboratory showed no sign of the pink fluorescence, which was found to be due to the presence of mercurous chloride, and you see here a sample with a most pleasing pink fluorescence. I have since learnt that the same phenomenon has been observed by O. Wolf, *Chem. Zeit.*, 36, 197.

I must hurry through a few other demonstrations: distinction between vegetable and mineral oils; amber—genuine and artificial; uranium acetate and nitrate; salicylic acid; vaseline; ivory; natural and false teeth; some organic and inorganic pigments. The last fluorescence experiment is one which opens up for the laboratory a new field of titration work. It was suggested by work done by Mellet and Bischoff in detecting

obliterated and forged signatures on cheques etc. by exposing them to U.V. radiation. My only example is the titration of phosphates which I have found useful for muddy liquors. You have ordinary sodium phosphate in neutral solution, to which has been added a drop of a saturated solution of quinine sulphate. You will see that as long as the solution is alkaline there is but a trifling fluorescence, but the approach to acidity is heralded by an intensely blue fluorescence. This is due to the temporary, and eventually permanent, formation of the acid sulphate of quinine. I would suggest that the method may lend itself to the investigation of the mixing of reactive and other solutions.

Before leaving this side of our subject, I should like to indicate to you the scale of absorption of wave length 3000 to 4000 Å, from almost none to almost the whole spectrum, by various glasses, from vita glass to the latest synthetic resin glass; with 'crookes' glass occupying an intermediate position in this respect. The uranium glass by its fluorescence will detect the invisible ultra-violet rays anywhere.

Here you will see that when I place vita glass in front of the filter of U.V. glass there is no further diminution of fluorescence of the uranium glass. But when I substitute the vita glass by the resin glass the fluorescence of the uranium glass all but ceases. Both vita and resin glass are, of course, quite transparent in ordinary daylight.

There are many promising commercial applications of our rays, most of which are still in the experimental stage. One that has passed into daily practice is that of testing the fastness of colours on various fabrics, and perhaps even more interesting, the detection (and destruction) of mildew in wool. The slide I show here is a photograph of the cabinet used by the Woollen Research Association. I can recommend any of my hearers who are interested to visit the Exhibition now open at the South Kensington Museum. I may add that in this testing full and elaborate precautions are taken to give the effects of humid air.

The sterilisation of water on the large scale has been accomplished for public baths and for potable water.

Aliphatic alcohols have been chlorinated, using U.V. radiation as activator, but I have no personal knowledge as to the success on the works scale.

I should like, but that the hour forbids, to relate work which biochemists have done upon the so-called "activation" of various food substances and pure substances such as cholesterol, or their still more fascinating attempts to prepare the elusive vitamin by this means.

Work is awaiting the chemist and physicist in the measurement of the intensity of U.V. radiation. Its quality and its relative intensity can, of course, be determined with considerable accuracy by a combination of quartz spectro-photometer and spectrograph. This excellent photograph was taken for me by Dr. Judd Lewis when I was at work on the decomposition by U.V.R. of pure carbon tetrachloride. I know no method which will enable me to state intensity of the radiation from an arc in terms of ergs. I am waiting to know the heats of formation of carbon hexa- and tetra-chloride. Many and varied methods of testing have been published

for comparing the intensity of one's lamps at different times and of investigating the intensity after passing through filters. Of these simplest to use, I may mention Dr. Leonard Hill and Dr. Eidenow's methylene blue test which you will see before you and Messrs. Moss and Knapp's oxalic acid and uranium acetate test. The carbon tetrachloride test, to which I have already referred, and which I have simplified for medical men's use, is suitable for rays below 2750 Å. Not one of them is perfect. Carbon tetrachloride may be used as a filter, fairly accurate in stopping rays below the figure given. The trouble with all actinometers which depend upon chemical action is that the co-efficient of extinction changes with the accumulation of decomposition products. My own method, when using carbon tetrachloride as a filter, is to pass a constant stream of it through the quartz cell you see here. I cannot discuss the more scientifically accurate methods involving the use of spectroscope and bolometer, and of the photoelectric cell employing colloidal forms of the alkali metals. Potassium is peculiarly sensitive to the blue violet spectrum and cadmium to the ultra-violet nearer the visible end. There is still room for improvement in the second type.

Mercury vapour lamps gradually fall off as regards the intensity of their emitted ultra-violet rays, and their effective life will depend upon the purpose for which they are used. For therapeutic purposes the "atmospheric" type has an average "life" of about 1000 hrs. Then they will need cleaning: an operation the chemist can do for himself. Eventually a new arc tube will be fused in. The actinometer will indicate with certainty when these attentions are desirable.

Mr. A. W. Knapp remarked that Mr. King still spoke of ultra-violet *light*, although the radiation was invisible. It was pleasant to note that although the modest ultra-violet was born to blush unseen, it was receiving a great deal of attention. Considering that we had at present no method which gave us at once the quality and quantity of the radiation, that was the intensity of each wave length, and that doctors must have very little knowledge of the differences in the radiation given by different sources, it was remarkable the results they achieved. For example, the mercury vapour lamp and the carbon arc gave very different spectra—presumably they produce different therapeutic effects! Again, an old mercury vapour lamp would not only give a less intense radiation than a new one, but also a different mixture of rays.

What was the relation of the intensity of the radiation from a mercury vapour lamp to that of June sunshine? It seemed to him it might be more economical to spend one's money not on ultra-violet treatment, but on a holiday on the South Coast. Mr. King's modification of the mercury vapour lamp promised to be very useful, but it would be of still greater use in the laboratory if he could send the rays vertically down, as then one need not use expensive quartz vessels to hold solutions etc. Mr. King had suggested that the Moss and Knapp method of measuring ultra-violet radiation suffered because it did not measure particular rays. Perhaps he did not know that it had been shown by absorption spectra of the depth of solution used in the test, that the range of rays which were measured was from 320 μ

That was important, because it was in just that range that there occurred those rays which produced the therapeutic and bactericidal effects, and therefore the method should prove of great use to doctors and others.

CALENDAR OF FORTHCOMING EVENTS

- June 17** SOCIETY OF CHEMICAL INDUSTRY AND THE INSTITUTE OF CHEMISTRY, *Newcastle Section*. Armstrong College, Newcastle-on-Tyne, at 6.30 p.m. The Second Bedson Club Lecture on "The photo synthesis of naturally occurring compounds," by Prof. E. C. C. Baly.
- June 17 & 18.** ASSOCIATION OF ECONOMIC BIOLOGISTS. June Meeting, The South-Eastern Agricultural College, Wye.
- June 18.** NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. General Meeting, at 2.30 p.m.
- June 23.** SOCIETY OF CHEMICAL INDUSTRY AND INSTITUTE OF CHEMISTRY, *Edinburgh and East of Scotland Sections*. Visit to Messrs. Webb & Co.'s Crystal Glass Works, Norton Park, Edinburgh, at 3 p.m.
- June 29.** ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2., at 4 p.m. Annual General Meeting.
- July 4 to 9.** SOCIETY OF CHEMICAL INDUSTRY. Forty-sixth Annual Meeting in Edinburgh. (*See CHEM. AND IND., May 20, 1927, p. 464.*)
- July 4 to 8.** SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual Meeting in Edinburgh. "Some aspects of the manufacture of fibrous cellulose," by Dr. J. L. A. Macdonald. A discussion will follow.
- July 15 & 16.** INSTITUTION OF SANITARY ENGINEERS. Annual General Meeting and visits in Birmingham.
- Aug. 20.** NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, Newcastle-upon-Tyne. Annual Meeting at 2.30 p.m.
- Aug. 31** BRITISH ASSOCIATION FOR THE ADVANCEMENT OF TO SEPT. 7. SCIENCE. Annual Meeting (97th year) at Leeds.

CANADIAN PULP AND PAPER

The St. John Power & Paper Co., is preparing to erect a 200-ton newsprint mill on the upper end of Lake St. John, Quebec, on the Mistassini river, about 21 miles from St. Felicien. The mill will cost about \$6,000,000.

The International Paper Company is negotiating with the government for a pulpwood limit on the Nelson river, Manitoba, and for the power site at White Mud Falls, the greatest water power site in Canada, not excepting Niagara Falls. The company already possesses about 1,657,699 acres of freehold pulpwood lands and 11,099,528 acres in crown timber limits under lease, all situated in Quebec, New Brunswick and Newfoundland. The company owns, in the U.S.A. and Canada, 27 pulp and paper mills, 7 hydro-electric power plants, and 12 saw-mills.

The physical testing, chemical laboratory and wood preservation department of the Forestry Laboratory of the Dominion Government is being removed from Montreal to Ottawa. The pulp and paper department will remain at McGill University.

BIOCHEMICAL SOCIETY

A meeting of the Biochemical Society was held on June 11 in the Biochemical Department of The Museum, Oxford, when the following papers were read:—

"The digestion of carbohydrates in the cockroach," by V. B. Wigglesworth.—The p_H of the saliva of the cockroach (*Blatella germanica*) has an average value of 6.9, and that of the contents of the mid-gut 6.3. The reaction of the crop, where digestion is mainly carried on, is dependent on the food, being about 6.2 with protein food and 5.0 with carbohydrates, the acidity in the latter case being due to the action of micro-organisms, especially yeasts, upon sugar. The enzymes of the cockroach have been compared with those of yeast and of the human jejunum. The amylase of the salivary glands and the invertase, maltase and lactase from the gastric caeca and mid-gut all have an optimum zone of p_H from about 5.0 - 6.2, being adapted to work at the reaction normally present in the crop. With this exception their properties are closely similar to those of the enzymes with which they have been compared. They are, for example, similarly affected by neutral salts, by heavy metals, by glycerol, and by various adsorbent materials.

"The Erlenmeyer amino-acid synthesis," by C. R. Harington and W. McCartney.—As observed during the synthesis of thyroxine (*Biochem. J.*, 1927, **21**, 169), the Erlenmeyer amino-acid synthesis may be modified by direct conversion of the benzoylamino-cinnamic acid (or ester) into the amino-acid by boiling with hydriodic acid and red phosphorus. In the case of β -[3, 5-diiodo-4-(4'-hydroxyphenoxy)phenyl]- α -aminopropionic acid, the yield of 25% first recorded has been improved more than three times by the further simple modification of using a mixture of equal parts of constant boiling hydriodic acid and acetic anhydride. The method has been applied successfully to the synthesis of the following amino-acids, the yields being constantly higher than those obtainable by Erlenmeyer's original method, and the saving of time effected being very considerable. The yields are calculated on the benzoylamino-cinnamic acid or ester (it is a matter of experiment to decide which is the more suitable in any given case), which itself is always readily obtainable in good yield from the corresponding aldehyde. Phenylalanine 88%, tyrosine 60%, 3, 4-dihydroxyphenylalanine 45%, desiodothyroxine 61%, β -[3, 5-diiodo-4-(4'-hydroxyphenoxy)phenyl]- α -amino-propionic acid, 82%.

"The presence of a nucleotide in milk," by P. G. Marshall and H. D. Kay.—A substance containing adenine, a pentose and phosphoric acid, and corresponding in its chemical and physical properties with adenine nucleotide has been isolated from the filtrate after precipitation of the proteins of goat's milk. It is present in small quantities only—to the extent of some 3.3 mgm. per 100 c.c. milk. It appears to be the first of the phosphoric esters present in goat's milk to be definitely identified. So far it has not been found possible to isolate it from cow's or from human milk.

"Metabolism of glucose by kidney tissue *in vitro*," by J. T. Irving.—The metabolism of glucose by chopped kidney tissue *in vitro* proceeds at a rate which is probably linear aerobically, but is completely inhibited *in vacuo*. It is also markedly inhibited by cyanide.

The following papers were also read :—"The oxidation of uric acid by hydrogen peroxide," "The estimation of oxalic acid in urine," and "The estimation of oxaluric acid in urine," by P. C. Raiment; "The chemistry of phosphagen," by P., and M. G. Eggleton; "Synthesis of vitamin B (torulin) by yeast," by F. Hawking; "Use of norite in the concentration of torulin," by H. W. Kinnersley and R. A. Peters; and "The peptic digestion of gelatin," by R. M. Beck and R. K. Cannan.

During the tea interval demonstrations were given by V. B. Wigglesworth on "A colorimetric method for the determination of the p_H of minute amounts of fluid"; by J. Orr Ewing and V. B. Reader on "Synthesis of a bacterial growth factor by meningococcus"; and by J. H. Jeffree and B. T. Squires on "A simple fluorophotometer."

PHYSICAL SOCIETY

At the meeting of the Physical Society held on June 10, a paper on "The latent heat of evaporation of sulphur" was read by J. H. Awbery. The method employed for the determination of the latent heat at the boiling point (444.5°C) is based upon a measurement of the loss of weight in a vessel containing sulphur when electrical energy is dissipated in the vessel at a known rate. The value found for the latent heat is 79 cal. per gm. with an estimated accuracy of 2%. Previous determinations by other experimenters give values 362 cal. per gm. at 316°C . (Person), and 64.8 cal. per gm. (Beckmann and Liesche). The latter value is based upon an estimate, from chemical data, of the proportion of S_8 and S_6 molecules present, and the assumption is made that this proportion is the same in the vapour and liquid phases.

In a paper by P. K. Kiehlu on "Regularities in the spectrum of ionised neon," certain lines found by L. and E. Bloch and Dejardin in the spectrum of neon, developed by electron bombardment, are definitely assigned to singly ionised neon, and are shown to conform with Hund's theory of complicated spectra.

H. Lowery submitted a paper on "The refraction and dispersion of gaseous carbon tetrachloride." The refractive index of the vapour for the green mercury line ($\lambda 5461\text{\AA}$) is 1.001799, the result being corrected for density, so as to indicate the refractivity of the vapour containing the same number of molecules as 1 c.c. of hydrogen contains at N.T.P. The dispersion of the vapour over the range $\lambda\lambda 4800\text{--}6700\text{\AA}$ is represented by the relation $\mu - 1 = (13.543 \times 10^{27}) / (7831.7 \times 10^{27} - \nu^2)$, ν being the frequency of the light concerned.

A demonstration of the Schönherr-Hessberger nitrogen fixation arc was given by Capt. G. I. Finch. This comprised a working model of the arc, about 1 ft. long, useful for instruction purposes. The relative advantages and disadvantages of the Birkeland-Eyde, Paulin and Schönherr-Hessberger processes of nitrogen oxidation were briefly referred to. The principal objection to the last of these is that the limit of size of plant is reached with an electrical input of about 750 kw. Birkeland-Eyde plants utilising up to 6000 kw. are in operation at present. The erection of a plant consuming 8000 kw. is contemplated. This type of plant suffers from the handicap of high initial cost.

CORRESPONDENCE

VERBIAGE?

SIR,—The suggestion, made on p. 494 of your issue of May 27, 1927, is verbiage, in so far as a view is attributed to me which I cannot hold. My interpretation of the interaction of hydrogen chloride and hydrone and of the activity thereby developed does not resemble, in the least degree, the view which represents the product as an ionised oxonium salt. Ionisation in a solution, in my opinion, does not involve the freedom of any ion. I am not aware that the current view is as stated—that such a view has been advanced I know. To me it is interesting as a half-acknowledgment of my contention, at Leeds, in prehistoric times, that the compounds HCl and H_2O must be put upon the same footing: that it was absurd, in fact, to treat hydrone as a neutral.

Yours, &c.,

HENRY E. ARMSTRONG

PERSONAL AND OTHER ITEMS

Prince Ginori Conti is now in London on a short visit.

Prof. A. V. Hill, F.R.S., has been elected an Honorary Fellow of King's College, Cambridge.

Mr. E. J. Holmyard (Clifton College, Bristol) has been appointed Foreign Editor (England) of *Archivis di Storia della Scienza*, the Italian history of science quarterly. He will be pleased to receive articles for publication and books for review, and will supply any information about rates of subscription etc. Probable subscribers may obtain specimen copies on application.

Dr. A. Jaques has been appointed manager of the By-Products Department of the Shotts Iron Co., Ltd.

Preparations are being made for the celebration of the tercentenary of the discovery of oil in America at the Seneca Indian oil spring at Cuba, New York.

The late Dr. A. Liebmann, M.A., left £44,484, with net personalty £39,229.

The late Mr. C. Hovenden, vice-chairman and managing director of Hovenden & Sons, Ltd., wholesale perfumers, left £78,831.

Presentation to Mr. E. V. Evans

On his retirement from the office of Hon. Treasurer, Mr. Evans was entertained to dinner at the Connaught Rooms on Thursday, the 9th inst., by a large number of his colleagues on the Council, including the past-presidents, Mr. W. Reid, Sir William Pope, Dr. E. F. Armstrong, and Mr. W. J. U. Woolcock, and the now president, Mr. F. H. Carr. Mr. Evans was the recipient of a vellum book containing the signatures of the past and present members of council during his term of office, and of a cigarette case of precious metal, and of many grateful speeches acknowledging his services.

A Key to Specialised Information

Just as the practical utility of a book is impaired by the want of an index, so the vast aggregation of knowledge

that has been built up and is in many cases being added to day by day is largely lost to mankind owing to the lack of a master-key to its whereabouts. Throughout this country there are numerous centres of specialised knowledge and experience of the most varied description, whose existence has only to be known for them to prove of the greatest service to the world in general. It is with the object of bringing these to light and recording their salient features in concise form that the Association of Special Libraries and Information Bureaux is compiling a Directory under the editorship of Mr. G. F. Barwick, late Keeper of Printed Books at the British Museum. At a meeting which was held some time ago at the Royal Institute of British Architects, Mr. Barwick spoke on the present position of the work. It has been decided to go forward with the printing of a first edition of the Directory at midsummer of this year, but much still remains to be done. It is recognised that completion in any one subject is well-nigh impossible in so short a time. It would, however, greatly further this end if libraries, organisations, firms or individuals which have special information on any subject would communicate with the Association (38, Bloomsbury Square, W.C.1), at the earliest moment. This applies equally to the various bureaux of information established under one name or another in different parts of the country.

Chemical Industry Committee in France

The Comité des Industries Chimiques de France has been founded with the object of providing permanent contact between the chief chemical undertakings. The president is M. Level, of the Cie d'Alais, Froges et Camargue; and the vice-presidents are M. A. Bernheim (Comptoir des Textiles Artificiels), M. H. E. Boyer (Soc. Chim. des Usines du Rhône), Comte de Vogue (Cie de Saint-Gobain, Chauny et Cirey). The secretary is M. D. Agache (Etablissements Kuhlmann), the treasurer M. Lheure (Soc. de la Grande-Paroisse). The Soc. Ammonia, the Grande-Paroisse, the Huiles, Goudrons et Derivés have also joined the committee.

Vitamin Content of Stored Butter

Research work is being begun at Otago University, New Zealand, on the effect of storage on the vitamin content of butter.

The Treatment of Garbage

A new method of garbage treatment has been developed which, it is claimed, eliminates obnoxious odours, is more economical to operate, and produces a more valuable product than other methods. This new process is a dehydrating treatment, following which grease is extracted by means of naphtha. About 25% more grease is recovered by this method than by former methods, and the residue is secured in the form of a solid substance which can be readily ground for fertiliser. U.S. Patents for this process have just been issued to Dr. R. D. McLaurin, air filtration purification expert, and C. G. Smith, superintendent of the Cleveland Municipal Garbage Disposal Works.

The Toxicity of Benzol

Field studies carried out in the United States (*J. Ind. Hyg.*, Feb., 1927) have indicated that the use of benzol

as an industrial solvent is attended with health hazards which can only be avoided by the provision of local exhaust ventilation and the maintenance of a system of medical supervision. Laboratory investigations have shown that certain of the higher homologues of benzene, such as toluol and xylol, are relatively free from the special hazards which attend the use of benzene. These substances, in large doses, are even more powerful narcotics than benzene, but their low volatility and marked odour make it unlikely that they will occur in workroom air in sufficient concentrations to become harmful, whilst they are almost wholly lacking in the specific effects on the nerve tissue and blood-forming organs which are characteristic of benzol.

The German Dye Trust

The I.-G. has filed papers of incorporation in Louisiana, U.S.A., as it is intended to erect a plant at Monroe, in the centre of the natural gas area.

Three new units are being erected at the Leuna Werke, the nitrogen-fixation plant of the I.-G. The present capacity is 300,000 tons of fixed nitrogen per annum. The coal hydrogenation plant is practically finished, and small-scale working is believed to have begun. The "Nitrophoska" plant, which makes the new complete fertiliser, will, it is expected, produce 10,000 tons a month, while the new calcium nitrate plant, also at Leuna, will probably turn out 10,000 tons a month of this new mixed fertiliser.

It is reported that a cheaper process has been developed for producing hydrogen, the hydrogen-containing raw gases being led over lignite mined on the spot, instead of coke.

The I.-G. is reported to have obtained control of the Cia. Nacional de Colorantes y Explosivos, the Spanish dyestuffs company, which produces some 300 tons azo dyes and 400 tons sulphur blacks, its intermediates being produced in excess of requirements in a factory at Barcelona.

At the general meeting of the I.-G. Farbenindustrie (the German Dye Trust) held on June 2, a dividend was declared of 10%. It was stated that the new plant for the liquefaction of coal at Merseburg was already working, the results so far achieved having come up to expectations, giving promise of satisfactory development. The total number of the Trust's employees was 67,760 workmen and 20,292 clerks, an increase of 2500 compared with last year.

New Aluminium Alloy

It is announced that a new aluminium alloy has been produced by the Central Aerodynamic Institute at Moscow. The alloy, known as "K.A.," is claimed to represent a considerable advance on duralumin, and is being used for the construction of aeroplanes.

New German Cutting Alloy

The Röchling-Buderus A.-G., of Wetzlar, has put on the market a new cutting alloy, "Miramant," containing molybdenum and tungsten, which is claimed to render possible the working of materials hitherto considered unworkable or commercially hard to work. The alloy is said to have given good results with manganese steel, chrome nickel steel, etc.

Note from Germany

The *Gewerkschaften Sachtleben* and *Sicilia*, of Cologne, and the *Schwarzwalder Barytwerke Schulte & Co.*, of Wolfach-Baden, have amalgamated to form a new company, the "Sachtleben" A.-G. für Bergbau und Chemische Industrie, with headquarters at Cologne.

Third Census of Production (1924)—Paper Trade

The returns for the paper trade show that the total value of goods made and work done in 1924 was £36,495,000, as compared with £15,956,000 in 1912, and £13,621,000 in 1907. This total value includes during 1924 printing paper valued at £17,704,000; writing paper at £5,189,000; packing and wrapping paper, £3,307,000; coated papers, £3,082,000; tissue paper, £982,000; blotting paper, £373,000; paper, other than printing, writing, packing and wrapping and coating papers, £2,648,000, and other papers £2,388,000.

It would appear that, taking the output as a whole, prices in 1912 were about 10% below those of 1907, and that in 1924, prices were about double those of 1912, or 80% higher than in 1907. With a view to obtaining a more exact record of the quantity of paper and board made in the industry, manufacturers were required to state their total make in the year 1924, whether the paper or board was sold as such or was used by them in the manufacture of bags, boxes, etc., during the year of return. The aggregates returned for each class were 22,706,200 cwt. of paper of all kinds made; 2,135,000 cwt. of cardboard and pasteboard; 106,800 cwt. of millboard; 29,900 cwt. of strawboard; and 77,000 cwt. of leatherboard, making a total of 25,054,900 cwt. The total weight of paper and board made in the year 1907 was not required to be stated by manufacturers, but was estimated as about 17,000,000 cwt. The total weight of paper and board made in 1924 exceeded that made in 1912 by about 23%, whilst the increase in output between the years 1907 and 1912 was about 20%. Taking the main classes of output separately, it appears that since 1907 a progressive increase has occurred in the production of printing paper, of cardboard, millboard, etc., and of unclassified products, such as boxes and other manufactures of cardboard, whereas the output in 1924 and in 1912 of packing and wrapping paper shows a decline compared with the previous survey. Of the total make of paper in the year 1924 (22,706,200 cwt.), about 18% was exported in the form of paper, while out of the 2,348,700 cwt. of cardboard, millboard, etc. manufactured, only 156,500 cwt., or under 7%, were exported as such. Retained imports of paper were nearly 39% of the total quantity manufactured in this country, whilst those of millboard, strawboard, etc. very largely exceeded the home production.

The total quantity of paper of all kinds available for use in the United Kingdom during 1924 may be roughly stated as 27,300,000 cwt., of which at least 17,000,000 cwt. consisted of newsprint and other printing paper. The quantity of news paper available amounted to about 30 lb. per head of the population, and of other printing paper to 14 lb. per head, of writing paper to about 5½ lb. per head, and of wrapping and packing papers to 17 lb. per head. In 1912 the quantity of paper that was available for writing or printing per head of the

population was about 40 lb., and that of packing and wrapping paper amounted to about 14.7 lb. The net output of the factories covered by returns amounted to £12,814,000, that sum representing the amount by which the total value of the output (£36,495,000) exceeded the cost of the materials purchased and used (£23,681,000).

The net output per head of persons employed during 1924 was £253, in 1912 £126, and in 1907 £111. The average number of persons employed in 1924 at the factories included in the returns was 50,707, of whom 47,351 consisted of operatives, and 3356 of management, clerical and technical staff. In 1907 the number of persons employed was 40,356, compared with 41,454 in 1912. The total capacity of engines at the factories in 1924 was shown as 242,518 h.p., a little over 12% of this total being idle or in reserve during the year. The capacity returned in 1912 was 189,432 h.p., and in 1907 168,274 h.p. The capacity of electric generators in the industry in 1924 was 79,032 h.p., compared with 32,075 in 1912, and 14,914 in 1907. There were also returned for the year 1924 electric motors of a total capacity of 108,374 h.p., driven by electricity generated by engines at the factories. Of these motors nearly 16% were in reserve or idle during the year. The total capacity of motors driven from firms' own dynamos in 1912 was returned as 33,970 h.p.

Third Census of Production (Artificial Silk Trade)

In 1924 the output of artificial silk, inclusive of artificial silk used by the makers as material in the manufacture of more finished goods, amounted to 25,525,000 lb., compared with 3,000,000 lb. in 1912. Figures are not available for the 1907 output. Exports of artificial silk from the United Kingdom during 1924 were 6,351,000 lb., and net imports 10,151,000 lb., or about 25% and 40% respectively of the quantity produced in that year in Great Britain. The total quantity of artificial silk available for consumption in the United Kingdom was thus 29,325,000 lb., rather over 65% being of home production and nearly 35% imported. The total quantity of thrown silk and spun silk yarn available for use in the year was estimated to have amounted to approximately 2,550,000 lb. The net output of the factories and workshops engaged in the silk and artificial silk industry during 1924 was £9,997,000, that sum representing the amount by which the total value of the output (£19,784,000) exceeded the cost of materials purchased and used (£9,167,000), and the value of work given out (£820,000). The net output per person was £255 in 1924, £72 in 1912, and £55 in 1907. The average number of persons employed during the year 1924 in the industry was 39,211, compared with 31,668 in 1907, and 34,500 in 1912. The total capacity of engines engaged in the industry in 1924 was shown as 35,949 h.p., of which slightly over 20% was in reserve or idle during the year. The capacity returned in 1912 amounted to 23,599 h.p., and in 1907 to 18,848 h.p. The capacity of electric motors at factories in 1924 was 17,732 h.p., driven by purchased electricity, about 21% of the capacity of these motors being in reserve or idle during the year. The capacity of electric generators in the industry in 1924 was 16,910 kw., compared with 1660 kw. in 1907.

REVIEWS

THE CHEMISTS' YEAR BOOK, 1927. Edited by Dr. F. W. ATACK. Pp. 1179. Manchester: Sherratt & Hughes. New York: The Chemical Catalog Co., Inc. Toronto, Canada: The Westman Press, Ltd. 1927. Price 21s.

Dare one propose a change of title? Why not The Chemists' Daily Book, for this is no year book. It contains no calendar, no diary, and it is in daily use year in, year out; an old and tried friend. Perhaps it is because one knows it and uses it so well that one is more critical of it than of less important works. Critical with a difference, because one asks so much of it, and would fain ask more; critical, too, because criticism is asked for and welcomed if helpful, and that is surely the desire of every user of this book.

Generalisations about so comprehensive a work as this are well-nigh futile, and the ground covered is such that no one man is competent to deal with the whole. What can be done is to draw attention to the particular wants one has noted and failed to satisfy, in the hope that space may be found in later editions to fill the lacunæ. And here are some of them.

In the section on viscosity (p. 19) no mention is made of the falling sphere viscometer, now so largely used in industries using viscous liquids, and mention might also be made of the work of the British Engineering Standards Association specifications, which have done so much to co-ordinate industrial viscosity methods and measurements.

The paragraphs on X-ray analysis (p. 199) might be expanded and reference made to the volume of important work done since 1919.

In the list of properties of organic compounds, a remarkable omission is the commoner citrates. The acetates, oxalates and tartrates are included, and the citrates are of sufficient importance to find a place.

It is doubtful whether the earlier part of the section on qualitative analysis, *e.g.*, pp. 517-527, serves any useful purpose, and one can but think that the space might be utilised in amplifying the specific tests given for some of the acids. It is not sufficient to say (p. 546): "Tartrates, malates, and citrates: In presence of these hydroxy acids, ferric chloride does not give a precipitate on addition of alkali." One must plead for specific tests in a book of this description. It is exactly that class of information which is looked for.

In the section on volumetric analysis a notable omission is any discussion of indicators; that, possibly, is to be incorporated in the section on the determination of p_H which is promised in the preface. Whilst discussing indicators it may be pointed out that the choice given in the paragraphs on silver nitrate and ammonium thiocyanate, potassium ferrocyanide and sodium sulphide do not generally commend themselves in technical practice, being replaced by iron alum for thiocyanate, ammonium molybdate for ferrocyanide, and ferric hydroxide for sodium sulphide.

In the section on organic analysis some mention should be made of the micro-methods which in so many laboratories are rightly superseding the older procedure; and with this mention of micro-methods may not a

plea be uttered for a larger recognition of microscopic methods in qualitative analysis. There can be no comparison between the old crude test-tubing and the modern micro-chemical tests. The beauty, certainty, and economy of micro-chemical tests has not been sufficiently advocated or taught, and one does appeal to the editor of this book to help in that direction if it be at all possible.

In the section on electro-chemical analysis one sentence surely needs excision. Page 628, "Accumulators are invariably used for electro-chemical analysis."

In spectroscopy it is doubtful whether anyone to-day uses the old arbitrary scale, and the space occupied by it might well be devoted to a fuller list of the standard lines of the iron arc and the mercury-vapour arc spectrum, both of which are so frequently used for calibration purposes.

Cellulose and paper bulk largely to-day in industry, and we could wish that a little fuller details had been given of the commoner sizing reactions, and that in the section on textile fibres the various staining tests had been included. Reference might also have been made to Sindall's book on "Paper technology" and Matthews, on "Textile fibres."

In the section on the examination of blood (p. 1060) staining is mentioned, but no detail is given apart from an obsolete method of permanent mounting. One at least of the modern differential stains might be included, and it might be well to mention one or other of the micro-methods of estimating sugar in blood, which have become so important an adjunct to the insulin treatment of diabetes.

In conclusion, welcome to the new edition, and may every year which passes see the book fuller, more complete, and more perfect. In this spirit the above criticisms are offered.

H. W. GREENWOOD

ENEMIES OF TIMBER: DRY ROT AND THE DEATH-WATCH BEETLE. By E. G. BLAKE, M.R.S.I. Pp. xii + 206. London: Chapman & Hall, Ltd., 1925. Price 12s. 6d.

In this book an account is given of the two worst enemies of timber, together with a thorough discussion of the damage that they cause, and of the methods for destroying them. The book opens with a chapter on the decay of timber, the remaining being divided into two sections, the first dealing with dry rot, the second with the death-watch beetle. The treatment is thoroughly practical, and the description of the methods of control is very full. Such a book should have a valuable educative influence, and as it is written from the view-point of the user of timber, should appeal to all who realise that much of the present waste of timber is preventable.

MICROSCOPIC FRESH WATER LIFE. By F. J. W. PLASKITT. Pp. xi + 278. London: Chapman & Hall, Ltd., 1926. Price 13s. 6d.

This book consists of an account, written by an experienced naturalist, of the micro-organisms found in fresh water. The treatment is popular, and the English is reasonably clear, though awkward constructions are too frequent. The organisms covered include aquatic

plants, algæ, diatoms, desmids, infusoria, rotifera, bugozoa, entomostraca, hydracarina, and so on. For those interested in the flora and fauna of fresh water, the book provides a handy introduction to the subject. There are numerous illustrations, both line drawings and photographs, of varying merit, and the book is well produced.

ANORGANISCHE CHEMIE. By Dr. ROBERT SCHWARZ. *Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe*, edited by Dr. R. E. Liesegang. Band XVI. Pp. xi+139. Dresden and Leipzig: Theodor Steinkopff, 1927. Price: paper, 8 m.; bound, 9.50 m.

This "report of progress," which forms a convenient adjunct to the text books, is concerned almost entirely with experimental inorganic chemistry; the complex compounds are briefly considered, but the section dealing with theoretical matters—molecular structure, theories of colour, etc.—is limited to 12 pages. Hence, although in a sense the book is self-contained, it is rather a fractional part of a general survey, other volumes of the series dealing with atomistics, analytical, physical, colloid, organic chemistry, etc. The period under review, 1914—1925, seems, within the apportioned limits, to have been reasonably well covered, and the text bears evidence of critical selection and consideration. If it be remembered that such a book is a handy guide to the literature rather than a substitute for it, the picture which it presents of the advance of knowledge will be found to be of more than ephemeral interest and value.

A. A. E.

CHEMISTRY IN THE WORLD'S WORK. By H. E. HOWE. "Library of Modern Sciences." Pp. vii+244. London: Chapman & Hall, Ltd., 1926. Price 15s.

Mr. Harrison E. Howe, a well-known American editor and author, has given, in his latest book, a stimulating account of the part played by chemistry in modern civilisation. Starting with the contributions which chemistry has made to the reduction of human isolation, both physical and mental, the author discusses the work of chemists in relation to fuels as "allies of the sun," food and famine, clothing, decoration ("Escape from monotony"), materials of construction, the fight against corrosion and decay ("Permanency of possessions"), sanitation and health, power, the abolition of drudgery, national defence, and concludes with suggestive chapters on chemistry as a tool, analysis and synthesis, and the trend and purpose of modern research.

The author has successfully avoided the pitfalls presented by the wealth of material available, and has both chosen his subjects and discussed them in such a way as to make a story which is both impressive and cumulative in effect. Eminently readable, the book, though not without its purple patches, makes a worthy companion in the "Library of Modern Sciences" to the volume previously contributed by Arrhenius. The book is primarily intended for the layman interested in the development of our modern civilisation, but the ground covered is so wide, and the treatment so interesting, that it will appeal to more than the merely curious.

PARLIAMENTARY NEWS

Gas Mantles

The following new clause is proposed in connexion with the Finance Bill: The Customs Duty imposed under the Safeguarding of Industries (Customs Duties) Act, 1925 (Geo. V., c. 79), mantles for incandescent lighting, whether collodionised or not, shall be reduced from six shillings the gross to one shilling the gross as from the first day of August, 1927, and the Customs Duty imposed under the same Act on impregnated hose or stockings for use in the manufacture of such mantles shall be reduced from four shillings and sixpence the pound to sixpence the pound from the first day of August, 1927.

British West Africa (Oil Palms)

Mr. Amery informed Sir John Power that last year agricultural officers of Nigeria and the Gold Coast were sent to the East Indies to study and report upon the methods in use there for improving the yield of oil palms. They had now returned, and were submitting their reports to the Governments of Nigeria and the Gold Coast, who were giving close attention to the problem of improving palmeries by planting better-yielding varieties and improving methods of native extraction. Discussions in regard to the establishment of central mills were in progress.—June 13.

Oil Drilling in Iraq

In reply to various questions, Mr. Amery stated that drilling for oil had actually taken place in Iraq, but he was not in a position to give details of the operations of individual oil companies. The Turkish Petroleum Company did not start drilling operations until April 5 last, and any statement as to results would be premature. The Anglo-Persian Oil Company was drilling near Kharakan, and the Turkish Petroleum Company was conducting its investigations in the old Mosul vilayet.—June 13.

COMPANY NEWS

BRITISH CELANESE, LTD.

The report for the year ended February 28, 1927, shows trading profit amounting to £793,850, an increase of nearly 68% over that for the previous year. The net profit, subject to depreciation, amounted to £223,193, which it is proposed to place to the credit of the depreciation reserve account, making that account £536,932. The loan of £50,000 from the Government was reduced by £10,000 during the year, and the balance of £40,000 has since been repaid. At the end of the year the company had a greater production and a larger turnover than ever before during its existence, supported by very substantial cash resources available for meeting all the company's foreseen requirements or for financing further expansion.

UNITED INDIGO AND CHEMICAL CO., LTD.

A dividend has been declared on the preference shares at the rate of 5% per annum, subject to tax, for the six months ending June 30.

BOOTS PURE DRUG CO., LTD.

The thirty-ninth annual ordinary general meeting was held on June 9, Mr. John C. Boot, J.P., chairman,

presiding. After briefly reviewing the accounts (cf. CHEM. AND IND., June 3, 1927, p. 515) the chairman said that the company had suffered from the general strike and the coal strike—fuel alone costing £10,000 more—the retail branches in mining areas being badly affected. With the exception of the new shop-fitting department, which was completed during the past year, the company had had no new manufacturing buildings for nearly ten years, and as the tonnage sent out from Nottingham had increased 22½% during the past three years, new factories were urgently required. Accordingly, the directors had bought 200 acres of land between Dunkirk and Beeston, which is within three miles of the Nottingham Market Place, and proposed to build a section for the soap and toilet departments and develop the remainder of the land as and when required. The sum of £100,000 had been set aside as a fund to provide for the expense of transferring departments to a new site. During the past year the scientific and research side of the business had been reorganised. The services had been secured of Dr. Pyman, hitherto Professor of Technological Chemistry in the University of Manchester and in the College of Technology, who will have control of the research laboratories. They had also persuaded Prof. Robinson, one of the most brilliant organic chemists of the day, to act as consultant to this department. Feeling the need for correlation of the purely chemical side of their work in the preparation of therapeutic substances with biochemical research and its application to clinical medicine, the company thought it of great importance to obtain some link with an up-to-date biochemical institute. In this they had been most successful, and acknowledged the valuable assistance afforded to their research department by the Middlesex Hospital, London, and, in particular, by the biochemical department of the Bland-Sutton Institute of that hospital. In recognition of this assistance they had endowed a scholarship in this institute. Total sales last year were the largest in the company's history. They had now over 800 shops open in Great Britain, and looked forward with every confidence to the future.

COURTAULDS, LTD.

A dividend has been announced on the 5% cumulative preference shares, payable on July 1 to shareholders registered on June 9.

MIRRELES BICKERTON AND DAY, LTD.

A dividend of 6% has been declared on the ordinary shares for the year.

NEUCHATEL ASPHALTE CO., LTD.

A dividend has been recommended of 9d. per ordinary share, less tax, making 1s. 3d. per share for 1926, being the same as for 1925.

ASBESTOS CORPORATION

The report for the eleven months ended December 31, 1926, shows operating profits of \$1,237,008, compared with \$781,979 by the old company for 1925, the net profits being \$596,673. Preference dividends absorbed \$391,445, leaving a balance of \$205,228 applicable to the common stock.

CROSFIELD'S OIL AND CAKE CO., LTD.

A final dividend has been declared of 5%, making 15%. The net profits amounted to £27,000.

ALEXANDER, FERGUSSON AND CO., LTD.

The profit made by this firm of lead smelters for 1926 was £18,318, plus £3535 brought forward, making £21,853. The sum of £4000 has been allocated to depreciation, and £4000 to reserve. Dividends have been declared on A and B ordinary shares at the rate of 12½%, plus a bonus of 2½%, carrying forward £2653.

TARAPACA AND TOCOPILLA NITRATE CO., LTD.

The twentieth ordinary annual general meeting, held on April 28, was presided over by the chairman, Mr. Edward Eyre. The gross profit for 1926 amounted to £37,927, the net profit being £3963, which has been carried forward. The total quantity of nitrate sold for shipment during 1926 was 13,473,848 metric quintals, against 24,926,009 metric quintals for 1925. The new oficina, "San Andres," was completed on February 14 last, and working operations were commenced on February 15. The old "Santa Fé" plant was closed on the previous day. The oficina was entitled to a monthly quota of 112,000 metric quintals, and this the company expected to get. A provisional iodine quota of 738·20 m.q. had been granted, and as this only represented 70% of the quantity that would be given when the Iodine House was completed, the company's effective quota should be 1054·6 m.q. The shareholders were to be congratulated upon possessing one of the best maquinas on the Pampa, and as the grounds were excellent, the cost of production should easily place them among the cheapest producers. It was thought that the average price for nitrate for the year July, 1927, to June, 1928, would probably be about 16s. f.o.b. Chile. Referring to the burden of the Chilean Government duty, the chairman said no trade could be maintained under such conditions. The company would continue working operations, although the returns would not, at any rate for the time being, yield the profits the investment of so large a sum of money was entitled to expect.

INTERNATIONAL PAPER CO., LTD.

The report of this company and its subsidiaries for 1926 shows total revenue amounting to \$9,834,543. Depreciation absorbs \$3,756,277, and interest on funded debt \$2,802,981, leaving a net revenue balance of \$3,275,283. Dividends on the preferred stock absorb \$2,198,471 and on the common stock \$750,000, leaving \$326,812, which with \$74,050 paid in surplus, makes a balance of \$400,862.

SWEDISH MATCH COMPANY

The final dividend for 1926 of 10 Swedish crowns per share has been paid at exchange 18·16 Swedish crowns to £ (11s. 0·158d.) per share, less British tax.

ALIANZA NITRATE CO., LTD.

The gross profit for 1926 was £29,900, the net result being a loss of £34,200. It has been decided not to recommend the payment of a dividend, but to carry forward £171,700 to 1927.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton. f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.
 Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.

Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals.—8d.—9d. per lb. Crude 60's, 2s. 4d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 2d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 8d.—2s. per gal. Pure, 1s. 10d.—2s. 3d. per gal.
 Xylol.—1s. 11d.—2s. 3d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—9d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 3d.—1s. 9d. per gal. Solvent 95/160, 1s. 5d.—1s. 6d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals.—£11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—70s.—80s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Naphthanic.—9d. per lb. 100% basis d/d.
 Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d. 1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum.—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—Cryst. £40—£43 per ton. Powder £44—£47 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s. 21s. per lb.
 Acid, Citric.—1s. 7½d.—1s. 8d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. 1s. 3½d.—1s. 5d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24—£27 per ton, Powder £26—£29 per ton, according to quantity, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 3d.—2s. 4d. per lb. Potassium.—1s. 10d.—1s. 11d. per lb. Sodium.—2s. 1d.—2s. 2d. per lb. All spot.
 Calcium Lactate.—1s. 2d.—1s. 4d. per lb.
 Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate.—6s. per lb.
 Ethers: Prices for Winchester quarts; dozen Winchester quarts; carboys or drums; and 10 cwt. lots respectively; 730—1s. 2½d.; 1s. 2d.; 1s. 1½d.; 1s. 0½d.; 720 tech.—1s. 5½d.; 1s. 5d.; 1s. 4½d.; 1s. 3½d.; 720 pur. (Aether P.B. 1914)—2s. 4d.; 2s. 3½d.; 2s. 3d.; 2s. 2d.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ¼ lb., 9s. 6d. per doz.; ½ lb., 6s. 6d. per doz.
 Hydroquinone.—4s. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perochloride.—4d. per lb., 22s. per cwt., according to quantity.
 Magnesium Carbonate.—Light Commercial £31 per ton net.
 Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic, 10s. 6d.—14s. 6d. per lb., according to quantity; Liquid (95%), 12s. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig. 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 9d. per lb.
 Methyl Sulphonol.—11s. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 4d. per lb.
 Phenacetin.—3s. per lb.
 Phenazone.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar 100s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d.—17s. 2d. per lb.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—4s. per lb. spot.
 Saccharin.—55s. per lb., and lower in quantity.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanoide.—4d. per lb., carr. paid.
 Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.
 Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.
 Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.
 Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.
 Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.
 Sulphonol.—7s. 6d. per lb.
 Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 3d. per lb.
 Thymol, Puriss.—10s. 3d.—10s. 9d. per lb., according to quantity. Natural.—12s. 6d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.
 Aubepine (*ex Anethole*).—10s. 6d. per lb.
 Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.
 Anethole (M.P. 21/22° C.).—5s. 6d. per lb.
 Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb.
 Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.
 Cinnamic Aldehyde.—Natural, 17s. per lb.
 Coumarin.—10s. per lb.
 Citronellol.—14s. 6d. per lb.
 Citral.—8s. 9d. per lb.
 Ethyl Cinnamate.—7s. 6d. per lb.
 Ethyl Phthalate.—2s. 9d. per lb.
 Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. Linalyl Acetate.—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.
 Methyl Anthranilate.—8s. 6d. per lb.
 Methyl Benzoate.—4s. 6d. per lb.
 Musk Ketone.—35s. per lb.
 Musk Xylol.—8s. 6d. per lb.
 Nerolin.—3s. 9d. per lb.
 Phenyl Ethyl Acetate.—12s. per lb.
 Phenyl Ethyl Alcohol.—10s. 6d. per lb.
 Rhodinol.—32s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanilin.—17s.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—30s. per lb. Bourbon Geranium.—14s. 9d. per lb.
 Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 6d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 1s. 11d. per lb., Ceylon, Pure, 1s. 9d. per lb. Clove, pure—6s. per lb.
 Eucalyptus, 75/80%.—2s. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. 3d. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz., Palma Rosa.—9s. 9d. per lb. Peppermint.—Wayne County, 17s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 6d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug. 6th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on June 23rd. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Andrews. Classification of powdered materials by elutriation. 14,547—9. May 30.

Boving. Apparatus for rarefying gases. 14,646. May 31.

Garland. Filters. 14,509. May 30.

Luck and Wood. Apparatus for supplying liquids in predetermined quantities. 14,845. June 2.

Mabag Maschinen u. Apparatebau A.-G., and Neuroth. Apparatus for degasification etc. of liquids. 14,754. June 1.
 Raw. Chemical etc. treatment of solid materials. 14,544. May 30.

Zahn & Co. Ges. Calcining-furnaces. 14,880. June 2.

I.—Complete Specifications

5383 (1926). Johnson (I.-G. Farbenind.). Manufacture of adsorbents. (271,564.)

5499 (1926). English and Hannan. Stills etc. (271,567.)

5615 (1926). Besta. Annealing metals, ceramic and other materials. (248,394.)

12,684 (1926). Berlin. Absorption refrigerating-apparatus. (271,634.)

24,434 (1926). Trocknungs-Verschmelzungs-u. Vergasungs Ges., Honigmann, and Bartling. Annular ovens or furnaces with rotating hearths for the treatment of pulverulent, granular, or like materials. (271,707.)

3820 (1927). Hänel. Grinding-mills. (271,780.)

7074 (1927). Pyrene Co., Ltd. Low freezing-point solutions. (267,561.)

8611 (1927). Roseoe. Machines for crushing ores, stone, rock, etc. (271,799.)

9349 (1927). Akt. Separator. Centrifugal separator installations. (269,883.)

*13,777 (1927). Akt. Elektrisk Malmletning. Discovering the position, configuration, and nature of ores, solutions of salts, etc. (271,871.)

*14,492 (1927). Ver. Stahlwerke A.-G. Grinding and milling machines. (271,904.)

II.—Applications

Chilovsky. Manufacture of gas from heavy oils. 14,536. May 30. (Belg., 16.7.25.)

Coley. Apparatus for activating carbon etc. 14,733. June 1.

Dupuy. Heating gases etc. 14,620. May 31. (Fr., 18.6.26.)

Générateur Rex Soc. Anon. Gas-producing apparatus. 14,505. May 30. (Fr., 31.5.26.)

Hellmann. Ovens for treating fuels etc. 14,767. June 1. Ger., 8.6.26.) Ovens for treating fuels. 14,881. June 2.

Johnson (I.-G. Farbenind.). Catalytic production of hydrocarbons. 14,503. May 30.

Soc. Anon. Charbons Actifs E. Urbain. Analysis of mixture of gases etc. 14,873. June 2. (Fr., 24.7.26.)

Soc. Anon. des Fours à Coke Semet, Solvay, et Piette. Apparatus for dry-cooling of coke. 14,535. May 30. (Belg., 5.5.27.)

Turner. Carbonising etc. retorts. 14,640. May 31.

II.—Complete Specifications

4558 (1926). Portham, and Tangential Dryers, Ltd. Removal or separation from gaseous fluid of material suspended therein. (271,545.)

8089 (1926). Perelis. Treatment of mineral oils by heat to obtain lower-boiling oils. (271,601.)

11,992 (1926). Berrisford. Separating coal from dirt and like foreign substances. (271,633.)

13,762 (1926). Hodgson and Jones. Apparatus for generating oil-gas. (271,649.)

21,266 (1926). Heylandt. Obtaining and storing gases under pressure. (271,692.)

28,563 (1926). Trumble. Distilling solid carbonaceous material. (271,740.)

28,768 (1926). Raytheon Manuf. Co. Gaseous electric conduction apparatus. (263,108.)

33,077 (1926). Tully and Yeo. Manufacture of gas for heating and lighting purposes. (271,765.)

70 (1927). *Pétrole Synthétique* and Folliet. Converting methane gas into hydrocarbons of higher carbon content. (271,767.)

*19,303 (1926). Still. Eliminating sulphuretted hydrogen from gases. (271,805.)

*8300 (1927). *Holzverkohlungs-Ind. A.-G.* See VII.

*12,404 (1927). I.-G. Farbenind. A.-G. Means for the extraction of carbon dioxide from gaseous mixtures. (271,852.)

*12,771 (1927). *Rhenania-Kunheim Ver. Chem. Fabr. A.-G.* Roasting gas-purifying substances. (271,854.)

*14,147 (1927). Novelli. Combustion of pit-coal, lignite, etc. (271,889.)

*14,334 and 14,536 (1927). Chilovsky. Manufacture of gas from heavy oils (271,899 and 271,907.)

*14,442 (1927). *Prep. Industrielle des Combustibles (Soc. Anon.)*. Apparatus for crushing and mixing pitch. (271,903.)

IV.—Applications

L.-G. Farbenind. Manufacture of dyestuffs. 14,534. May 30. (Ger., 29.5.26.) Manufacture of α -anthraquinonyl ketones. 14,851. June 2. (Ger., 7.6.26.)

Imray (I.-G. Farbenind.). Manufacture of azo dyestuffs. 14,746. June 1.

Johnson (I.-G. Farbenind.). Production of dyestuffs. 14,504. May 30. Manufacture of azo dyestuffs. 14,828. June 2.

Scottish Dyes, Ltd., Hooley, and Thomas. Production of dyestuffs. 14,748. June 1.

IV.—Complete Specifications

1789 (1926). Wylam, Harris, Thomas, and Scottish Dyes Ltd. Dyes and dyeing. (271,533.)

2291 (1926). Smith, Thomas, and Scottish Dyes, Ltd. Dyes and dyeing. (271,537.)

5048 (1926). Johnson (I.-G. Farbenind.). See VI.

5522 (1926). Marschalk. Reducing vat dyestuffs to their leuco-derivatives. (271,569.)

5892 (1926). Marks (Du Pont de Nemours & Co.) Water-insoluble colours or dyes. (271,580.)

6615 (1926). I.-G. Farbenind. A.-G. Manufacture of α -keto- β -naphthols and of condensation products of the benzanthrone series. (248,791.)

8397 (1926). Brit. Dyestuffs Corp., Ltd., and Shepherdson. Manufacture of anthraquinone derivatives. (271,602.)

10,081 (1926). I.-G. Farbenind. Manufacture of azo dyestuffs. (253,488.)

*14,332 (1927). Soc. Chem. Ind. in Basle. See VI.

*14,333 (1927). Soc. Chem. Ind. in Basle. Manufacture of products applicable for making dyestuff preparations and of dyestuffs therefrom (271,898.)

*14,534 (1927). I.-G. Farbenind. A.-G. Manufacture of vat dyestuffs. (271,906.)

V.—Applications

Hägglund. Treatment of black liquor obtained in manufacture of wood fibre. 14,667. May 31. (Ger., 23.6.26.)

Moes. Manufacture of paper. 14,550. May 30. (Holland, 24.12.26.)

V.—Complete Specifications

29,917 (1925). Langwell, Ricard, and Burton. See XVIII.

4429 (1926). Imray (I.-G. Farbenind.). Grounding or padding of textile material. (271,543.)

5119 (1926). Kaye. See XIV.

9029 (1926). Phipps. Surface decoration of textiles. (271,008.)

10,025 (1927). Roura. Manufacture of product for treating the hair. (271,802.)

*13,123 (1927). Heberlein & Co. A.-G. Producing pattern effects on textiles. (271,859.)

VI.—Application

Huessy. Bleaching textile fabrics etc. 14,455. May 30.

VI.—Complete Specifications

1789 (1926). Wylam, Harris, Thomas, and Scottish Dyes, Ltd. See IV.

2291 (1926). Smith, Thomas, and Scottish Dyes, Ltd. See IV.

5048 (1926). Johnson (I.-G. Farbenind.). Dyeing cellulose esters and preparations for use therein. (271,550.)

*14,332 (1927). Soc. Chem. Ind. in Basle. Producing fast tints on vegetable fibres and manufacture of dyestuffs therefor. (271,897.)

VII.—Applications

Cerini. Apparatus for purification of solutions of caustic soda etc. 14,500. May 31. (Italy, 1.6.26.)

Coley. Manufacture of zinc oxide. 14,734. June 1.

Still and Still. Recovering sulphuric acid. 14,641. May 31. (Ger., 22.12.26.)

VII.—Complete Specifications

26,401 (1926). Metallbank u. Metallurgische Ges. A.-G. Production of sulphuric acid. (262,397.)

26,465 and 26,525 (1926). Reymerholms Gamla Ind. Akt. Utilising the liquors from chloridising roasting pyrites cinder etc. (260,294 and 260,297.)

*2202 (1927). Rütgerswerke-A.-G. Working-up fluorides containing silicic acid. (271,816.)

*8300 (1927). *Holzverkohlungs-Ind. A.-G.* Concentrating raw pyrolygneous acid. (271,828.)

*13,626 (1927). Weitz. Separation of alkali salts. (271,869.)

*13,777 (1927). Akt. Elektrisk Malmletning. See I.

*13,808 (1927). Titanium Alloy Manuf. Co. Obtaining zirconium compounds. (271,873.)

4881 (1927). Collin A.-G. zur Verwertung von Brennstoffen u. Metallen. Discharging ammonium sulphate from saturating-tanks. (268,309.)

VIII.—Applications

Holophane, Ltd., and English. Manufacture of glass for transmitting ultra-violet light. 14,542. May 30.

United Glass Bottle Manuf., Ltd., and Moorshead. Glass furnaces. 14,743. June 1.

VIII.—Complete Specifications

5615 (1926). Besta. See I.

32,847 (1926). Bicheroux. Manufacture of raw plate-glass. (263,846.)

*12,149 (1927). U.S. Metals Refining Co. Magnesite refractories. (271,847.)

IX.—Complete Specifications

1791 (1926). Hauts-Fourneaux & Acieries de Differdange-St. Ingbert-Rumelange Soc. Anon., and Lavandier. Calcining limestone and the like in vertical kilns fired with lean gas. (246,485.)

20,775 (1926). Cohen. Toughening and hardening artificial or natural stone. (271,722.)

6740 (1927). Michelsen. Conversion of slags into cement. (267,539.)

X.—Applications

Boës and Kröning. Steel-hardening baths. 14,500. May 30.

Cholevinski. Bearing-metals. 14,725. June 1. (Poland, 18.6.26.)

Greenway Bros., Ltd., and Greenway. Galvanising etc. metals. 14,562. May 31.

Harris. Mechanical ore-roasting furnaces. 14,784. June 2.

Pirovarsky. Cupola furnaces. 14,655. May 31. (Ger., 31.5.26.)

Siemens Elektrowarme-Ges. Annealing-furnaces. 14,645. May 31. (Ger., 3.6.26.)

Weichel. Cupola furnaces. 14,709. June 1. (Ger., 2.6.26.)

X.—Complete Specifications

- 5190 (1926). K&h. Furnaces for smelting and refining iron, steel, etc. (248,012.)
 5815 (1926). Besta. See I.
 7431 (1926). Clausson & Co. Akt. See XI.
 7637 (1926). Hybinte. Manufacture of a light aluminium alloy. (271,597.)
 8922 (1926). Chopra and Bullen. Heat-treatment of steel. (271,606.)
 16,377 (1926). Marks (Vergo Aluminium Metallverwertungs-Ges.). Solders for aluminium and aluminium alloys. (271,662.)
 27,449 (1926). Maschinenfabr. Esslingen. Making grey-iron castings of any desired structure. (260,990.)
 8502 (1927). Aluminium Co. of America. Production of corrosion-resistant articles. (271,798.)
 *20,269 (1926). Industrias Reunidas "Alba" Soc. Anon. Manufacturing metallic articles from molten metal. (271,806.)
 *12,435 (1927). Copper De-oxidation Corp. Pyrometallurgically refining and casting copper. (271,853.)
 *13,777 (1927). Akt. Elektrisk Malmletning. See I.
 *13,863 (1927). Soc. Gén. Métallurgique de Hoboken. Roasting of zinc sulphide ores. (271,877.)
 *14,655 (1927). Pivovarsky. Cupola furnace. (271,910.)

XI.—Applications

- A.-G. Brown, Boveri, et Cie. Electric furnaces. 14,861. June 2. (Ger., 7.6.26.)
 British Thomson-Houston Co., Ltd. Electric incandescence lamps. 14,629. May 31. (U.S., 2.6.26.)
 Jordan. Plating iron etc. 14,750. June 1.
 Northrup. Electric induction furnaces. 14,554. May 30.

XI.—Complete Specifications

- 7431 (1926). Clausson & Co. Akt. Electrodeposition of chromium and its alloys. (264,442.)
 8450 (1926). M.-O. Valve Co., Ltd., and Cosgrove. Electric discharge tubes. (271,603.)
 19,265 (1926). Allan. Electrolytic apparatus and electrodes therefor. (271,685.)
 26,646 (1926). Salles. See XXIII.
 26,895 (1926). Scott. Electrolytic apparatus and electrodes therefor. (271,726.)
 28,557 (1926). Armstrong, Whitworth, & Co., Ltd., and Windle. Electric furnaces. (271,739.)
 28,768 (1926). Raytheon Manuf. Co. See II.
 30,336 (1926). Gumlich. Magnetisable material. (262,153.)
 1701 (1927). A.-G. Brown, Boveri & Cie. Electric furnaces for heating gases at high temperatures. (264,849.)
 *31,418 (1926). Goltstein. Mercury-vapour lamp. (271,812.)

XII.—Application

- Pansky. Apparatus for extracting fats at low temperatures. 14,793. June 2.

XIII.—Complete Specifications

- 5746 (1926). Soc. Chem. Ind. in Basle. Manufacture of condensation products from carbamide or its derivatives and formaldehyde. (249,101.)
 6458 (1926). I.-G. Farbenind. A.-G. Manufacture of water-soluble condensation products. (248,782.)
 24,554 (1926). Palasseau. Manufacture of sticks, canes, etc. having a nacreous or metallic appearance. (259,249.)

XIV.—Complete Specifications

- 5119 (1926). Kaye. Vulcanised products for use in the manufacture of rubber goods, paper, or coated fabrics, etc. (271,553.)

- *13,366 (1927). I.-G. Farbenind. A.-G. Preserving rubber latex. (271,863.)

XVI.—Application

- Comp. de Prod. Chim. et Electrometallurgiques Alais, Froges, et Camargue. Herbicidal products. 14,825. June 2. (Fr., 25.6.26.)

XVIII.—Application

- Fox. Acetification of vinegar. 14,447. May 30.

XVIII.—Complete Specifications

- 20,917 (1925). Langwell, Picard, and Burton. Fermentation of cellulosic materials. (271,254.)
 3356 (1927). Hansena and Nathan. Treatment of yeast for use in the brewing of beer. (271,777.)
 *14,075 (1927). Levin. Preparing a preservable yeast preparation. (271,883.)

XIX.—Complete Specification

- 11,565 (1926). Haddan (Collins). Preservation of fresh fruit, vegetables, and like food materials. (271,626.)

XX.—Application

- Grasso. Treating organic fluids. 14,789. June 2.

XX.—Complete Specifications

- 2768 (1926). Audibert. Production of substantially pure methyl alcohol. (271,538.)
 5193 (1926). Danischevsky. Manufacture of pine extract. (271,555.)
 6615 (1926). I.-G. Farbenind. A.-G. See IV.
 6976 (1926). Synthetic Ammonia & Nitrates, Ltd., Smith, and Smith. Manufacture of acetic acid and acetates. (271,589.)
 19,031 (1926). Soc. Chem. Ind. in Basle. Manufacture of new compounds of gall acids. (257,900.)
 25,301 (1926). Deutsche Gold- u. Silber-Scheidanstalt vorm. Roessler. Production of β -pyridylhydrazine and its derivatives. (259,961.)
 26,806 (1926). McKee. Making peroxides of organic acids. (271,725.)
 70 (1927). Pétrole Synthétique, and Folliet. See II.
 *3022 (1927). Bots, and Soc. Anon. Prod. Chim. Coverlin. Manufacture of vanillin. (271,818.)
 *3023 (1927). Bots, and Soc. Anon. Prod. Chim. Coverlin. Manufacture of isoeugenol. (271,819.)
 *10,322 (1927). Etabl. Poulenc Frères. Manufacture of readily soluble organic salts of CC-dialkyl- and arylalkyl-barbituric acids. (271,837.)
 *10,647 (1927). Commercial Solvents Corp. Catalysts for synthetic methyl alcohol production. (271,840.)
 *14,056 (1927). Frischer. Producing volatile acids. (271,881.)
 *14,091 (1927). I.-G. Farbenind. A.-G. Manufacture of α -anthraquinonyl ketones. (271,884.)

XXI.—Application

- Martinez. Colour photography. 14,476. May 30.

XXI.—Complete Specification

- 5605 (1926). Wheeler. Colouring the image on photographic plates, films, etc. (271,578.)

XXIII.—Complete Specification

- 26,646 (1926). Salles. Electrolytically sterilising waters. (271,721.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference

number:—*British India*: Steel tubes, cast steel, malleable cast iron (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1.). *Canada*: Centrifugal electric pumping set (A.X. 4781). *Egypt*: Hides, leather (Egyptian Government, 41, Tothill Street, Westminster, S.W.1); Iron and steel, metals (A.X. 4723). *Holland*: Newsprint, printing papers (596). *Italy*: Leather (597). *Norway*: Copra, coconut and linseed oil, syrup (600). *Panama*: Paint, varnish, oils, corrugated galvanised iron (606). *Rumania*: Industrial chemicals, paper, leather (601). *Spain*: Cast iron piping (26964/27). *Switzerland*: Pharmaceutical products (603).

Gas-making Plant

The Gas Light & Coke Co., London, has placed an order with the Woodall-Duckham Vertical Retort & Oven Construction Co. (1920), Ltd., for an installation of continuous vertical retorts capable of making approximately 10 million cu. ft. of gas per day under ordinary working conditions, when carbonising unscreened Durham coals. The installation will comprise two benches, each of thirty-six 103-in. retorts. The contract includes coal and coke-handling machinery, and four waste-heat boilers, three of which will normally be working, leaving the fourth acting as a standby.

National Benzole Mixture

In view of the recent propaganda appertaining to Soviet petrol, the National Benzole Co., Ltd., wishes to make the position quite clear as far as its products are concerned. National Benzole Mixture is composed of benzole produced from British coal and petrol refined within the Empire. It is produced and distributed entirely by British labour, and exploited by British enterprise and capital. In short, it is completely British.

Sulphate of Ammonia

Nitram, Ltd., announces it has decided to continue selling sulphate of ammonia for home agricultural use until further notice, at the current prices of £12 6s. per ton for neutral quality and £11 16s. per ton for ordinary quality, delivered carriage paid in 4-ton lots and upwards to buyer's nearest station or ex works in 1-ton lots and upwards.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during May, has been furnished to the Board of Trade by the Dyestuffs' Advisory Licensing Committee. The total number of applications received during the month was 656, of which 542 were from merchants or importers. To these should be added 29 as set out tanding on April 30, making a total for the month of 685. These were dealt with as follows:—Granted - 582 (of which 555 were dealt with within 7 days of receipt); referred to British makers of similar products - 77 (of which 58 were dealt with within 7 days of receipt); referred to Reparation Supplies available - 3 (all dealt with within 2 days of receipt); outstanding on May 31, 1927 - 23. Of the total of 685 applications received, 616, or 90%, were dealt with within 7 days of receipt.

News from Advertisements

1. The City of Cardiff Education Committee announce a vacancy for a full-time assistant lecturer in pharmaceutical chemistry (p. ix).
2. A metallurgical chemist is required (p. ix).
3. Applications for appointment in the research laboratories of a manufacturing company will be considered from physicists or physical chemists (p. ix).
4. The Manchester Municipal College of Technology announce particulars of various courses (p. ix).
5. The University of Leeds announce courses in connexion with the Department of Coal Gas and Fuel Industries (with Metallurgy) (p. ix).
6. B.Sc. (Hons. Chem.) A.I.C. seeks position in laboratory of food factory (p. ix).
7. Chemist experienced in the manufacture of heavy chemicals, dyestuffs, and pharmaceutical products requires position (p. ix).

No. 25

EDITORIAL

The Annual Meeting at Edinburgh

THE Scots have been clever enough to envelope Edinburgh and other Anglo-Saxon cities and towns with a romantic haze of Highland glory. The hostility which prevailed for so many centuries between the townsmen who wore tweeds, and the clansmen who wore the tartan, has been followed by a successful effort to create a national pride in a number of heroes who detested and despised each other. The southern Scots have taken to themselves all the Highland virtues and now feel a superiority over the English north countrymen from whom they hardly differ in race, language or history. The City of Edinburgh is singularly fortunate in this romantic glory; founded by marauders from Schleswig and occupied by their descendants to this day, it has become a capital in which the kilt, the pipes and the claymore possess an air of respectability if not aristocracy. Edinburgh is sufficiently close to the wonderful Highland country to be familiar with the glories of Loch Tay and Loch Rannoch, of Schiehallion and Ben More; it is a city which is crowded with memories of Scott and Burns, and also with those of Mackenzie, Campbell and MacGregor. Edinburgh has its own volcanic hills to give an air of verisimilitude to its claim to relationship with the Highlands; it has in addition every charm necessary for a great capital, and the only disadvantage it possesses is that there is so much to see in Edinburgh that the lazy ones amongst us may not pay due regard to the improvement of our chemical knowledge. We have ourselves visited Edinburgh several times; the last time we saw it was after a rough voyage across the North Sea, a few weeks after the outbreak of war. There are still three chemical pilgrimages we have to make in Edinburgh, one to the home of Simpson, who discovered chloroform, one to the home of Gregory, the inventor of the famous powders, and one to the home of Napier, the mathematician, whose logarithms saved us so many hours nearly forty years

ago, when we used to perform with the retort and the balance. We are not sure which are the best things to see in Edinburgh; the natural scenery is undoubtedly striking; to literary or to legal folk the place is crammed with memories and anecdotes; any one can rejoice to see the fine paintings by Raeburn, and then we have ourselves to admire, and what for no? Conscious as we are of our own merits and each other's infirmities, we can demonstrate to Scotland and even to so cultured people as the academic society of the modern Athens, how much modern civilisation owes to the chemical industry. A few of the really earnest ones, biochemists and chemical engineers, will improve their minds; the President and members of Council have duties to perform; the editorial staff, having practically no duties to perform, and having improved their minds for a considerable period of time, now intend to relax them. We can hardly think of a pleasanter place for relaxation than Edinburgh; in its richness in historical and romantic associations it may be ranked with the most famous cities; in its proximity to a romantically beautiful country it excels, we think, all the capitals we have visited.

The Hydrogenation Pendulum

In the course of a few rare moments of delightful abstraction our thoughts strayed without restraint until the dignified tick-tock of an old grandfather clock fastened them upon the swing of the pendulum. By more or less inconsequential sequences, we passed to the recollection of a child's flight through the air from an improvised garden swing, to aeronautics, to Captain Lindbergh and Messrs. Chamberlin and Levine, to airships, helium and hydrogen. At hydrogenation, a reversion to the swing of the pendulum occurred, and we commenced to consider in earnest the changes which have taken place in hydrogenation practice and the latest suggestions for relatively low temperature processes.

The pendulum has swung many times since Sabatier, thirty years ago, first discovered the catalytic power of nickel in hydrogenation processes. Sabatier declared that the catalyst must not be wetted by condensation of the vapours undergoing treatment, but a few years later Norman demonstrated that oils could be hydrogenated in the liquid condition in the presence of Sabatier's nickel. Views as to the nature of the catalyst changed, and the original conception that metallic nickel was the active catalyst came back into favour after the Bedford and Erdmann school had pressed strongly for nickel suboxide. Ideas on the mechanism of the hydrogenation reactions have changed, too, since the classical work of Sabatier and his associates pointed to the intermediate formation of a hydride of nickel, and the Armstrong-Hilditch theory appears definitely to hold the field.

Right from the early days of oil hydrogenation, however, two facts have been known, namely, that the addition of hydrogen is a selective process, and that iso-oleic acid is produced during hydrogenation.

Iso-oleic acid is a solid unsaturated acid, and possesses undesirable properties considered from the point of view of the soap maker or the edible oil producer, the two most important consumers of hardened oils. In the hydrogenated oils required by the makers of compound lards, margarine and general edible fats the presence of acids more unsaturated than oleic—for example, linolic acid—is undesirable for well-established reasons, but as the selective hydrogenation of such acids is accompanied by the formation of large amounts of solid iso-oleic acid or acids, the melting point and texture of the fat obtained are unsatisfactory. Similarly, the presence of iso-oleic acids in soap makers' hardened oils involves the production of a soap with diminished lathering and detergent properties, especially in the absence of a highly intricate technique of blending. It is therefore unfortunate that up to the present it has been technically almost impossible to hydrogenate oils rapidly and economically without the formation of relatively large amounts of the solid unsaturated acids. Certainly the process of Bolton and Lush aims at establishing conditions such that iso-oleic acid formation is avoided to a large degree, and in view of its simple and continuous nature, it has an interesting future.

It might seem invidious at first sight to select from the hundreds of hydrogenation patents a single one for editorial notice, but the value of a catalyst which will facilitate hydrogenation at a low temperature and a high velocity can scarcely be over-estimated, for, as the ordinary temperature of hydrogenation is lowered, it is well known that iso-oleic acid formation is repressed. Thus it is that a recent specification of the I.-G. Farbenindustrie Aktiengesellschaft has attracted our special consideration. In this specification it is stated that many hydrogenation reactions can be conducted at a relatively low temperature and at a rapid rate, if a suitably prepared nickel catalyst be employed. Acetone is converted into iso-propyl alcohol in 95% yield at a temperature of 40°–70° C. Similarly, from pyridine at 110° C., piperidine is produced in almost quantitative yield, and it is quite within the bounds of possibility

that liquid vegetable oils may be capable of hydrogenation or hardening sufficiently rapidly for economic technical purposes without the formation of substantial amounts of iso-oleic acid by reason of the relatively low temperatures of reaction which it may be feasible to employ.

In the ordinary method of making nickel catalysts, the nickel compound to be reduced is precipitated upon a carrier in a more or less colloidal form. If, it is stated by the I.-G., the nickel compound is precipitated in a crystalline form, the catalyst subsequently produced is very active, even at relatively low temperatures. The nickel compound is precipitated upon the carrier at a raised temperature, and so slowly as to allow of a crystalline form being assumed by the nickel hydroxide or carbonate. For example, the carrier—powdered silicic acid gel—is suspended in a dilute solution of nickel nitrate, and a very dilute solution of sodium carbonate is added drop by drop during a period of 8 hrs., the temperature being maintained at 70° C. After filtration, washing and drying, the mass is heated slowly in hydrogen up to about 420° C., and after a suitable reduction time, a supported nickel catalyst is formed which is claimed to be highly efficient in hydrogenation operations conducted at temperatures much lower than those commonly employed in present practice. The swing of the pendulum in hydrogenation technique has shown much of interest. From operations conducted at ordinary temperatures and pressures, with the aid of the noble metals, sometimes in colloidal form, we passed with Sabatier to processes using reduced nickel at such temperatures as were sufficient to maintain organic compounds in the vapour state. Ipatiev employed metallic oxides at higher temperatures and raised pressures, whilst Norman showed how to hydrogenate liquid oils at 180° C. Brochet then applied liquid phase hydrogenation to phenol and other organic compounds, reduced nickel again being used. The noble metals came back in the technical application of supported palladium for oil hydrogenation, and later we saw the development of such processes as synthetic ammonia production, the manufacture of methyl alcohol from carbon monoxide and hydrogen, coal hydrogenation and the conversion of naphthalene into tetrahydro and decahydro derivatives, all of which demanded the employment of very high temperatures and pressures, and the creation of plant by modern metallurgists and chemical engineers which would stand up to pressures of a thousand atmospheres and temperatures of 500° C. simultaneously doing their worst. Finally, we have come back with the work of Fischer to the hydrogenation of carbon monoxide to paraffins at ordinary pressures with the aid of special catalysts and the hydrogenation of oils at such temperatures as repress iso-oleic acid formation by the process of Bolton and Lush, and, if the claims of the I.-G. are substantiated, by the use of specially prepared highly active nickel catalysts.

Tick-tock, tick-tock—the pendulum is still swinging, and if we read the signs of the times aright, the old clock is destined to turn his face upon more discoveries in a decade than he did in a century of his earlier life.

THE COMMERCIAL SYNTHETIC RESINS AND THEIR PRODUCTS

By HERBERT W. ROWELL

The manufacture of synthetic resins has become a chemical industry of such commercial importance that the volume of its demand for raw materials affects their market price. One firm in America is working a large synthetic plant to supply part of its requirements of pure phenol. In this country at least 30 well-qualified chemists are directly engaged in controlling plant and sales, or in research connected with the manufacture of synthetic resins, and probably over 300 chemists, together with a number of assistants, are so exclusively engaged throughout the world.

As a chemical industry it virtually ends with the manufacture of soluble resins, solutions or lacquers, and mouldable masses or powders. A second industry, now called the moulding industry, converts these raw materials into the finished article. It is not always good business policy to combine the two industries in one organisation, although no technical objection can be raised if the output of resin is sufficiently large.

The output of synthetic resins can only be very roughly approximated. A French authority in 1924-5 gave America as making 6000 tons per annum, Germany 3600 tons, France 1200 tons, and Great Britain was not mentioned, but these figures probably mean synthetic resin products, and they may be halved to arrive at the pure resin output. A report of the United States Tariff Commission mentions three firms producing a total of over 2000 long tons of pure resin in 1920. The present figures for pure resin output are in the region of: America, 6000 tons; Germany, 4000 tons; France, 600 tons; and Britain, 500 to 700 tons per annum. This means about 200 million moulded articles and hundreds of tons of resin-paper material, as well as other fancy goods, as the annual world output.

Synthetic resin products include many articles such as cups and saucers which are not easily broken, teapot handles which do not become hot, transparent fountain pens, clock cases, cigarette tubes, ash trays, telephone ear-cups, laboratory apparatus and toilet requisites, as well as a large variety of engineering and electrical components. They are made in all colours, either transparent, translucent or opaque. Synthetic resin of one kind or other is the essential ingredient in all of them, and it is not a mere substitute for other materials. Its peculiar properties enable articles of simple or complicated shape to be made rapidly by new and cheaper methods which give results unattainable by the use of the older materials.

By combination of suitable resin with suitable reinforcing and filling materials it is possible to make goods which do not soften on heating or decompose at temperatures below 350° C., do not swell or distort when boiled in water, are not attacked by tar, petroleum or vegetable oils, alcohol or the common organic solvents, 50% sulphuric, strong hydrochloric, hydrofluoric or organic acids, zinc chloride, copper sulphate and most salt solutions. Strong sodium carbonate and weak caustic solutions are without effect, but the resins are

soluble in strong caustic solutions, and are charred or oxidised by strong sulphuric and nitric acids.

Although modern types of hard rubber may be a more practical proposition in many cases, it is of interest to chemical manufacturers that tank linings, stirrers, pump casings and impellers, cocks, pipes, and the like can be made of light and strong synthetic resin compositions and stoneware parts or pipe joints can be cemented with them. Synthetic resin products should not be confused with articles moulded from mixtures of fillers bonded with shellac, bitumen, pitch, drying oils and the like, which soften when heated and which may be identified by their characteristic smell when held in a flame. Some hard rubber goods like ebonite, casein goods like erinoid, and nitrocellulose goods like celluloid have a similar appearance to the synthetic resin goods, but have not the same desirable properties. The term "synthetic resin" is a misnomer, for these compounds have no chemical relation to the natural resins and few physical properties in common with them, but we continue to use the term until a better generic name is discovered. Many names, such as Bakelite, have been invented as trade marks and add to the confusion. The same name is used indiscriminately by a maker to describe not only a particular make of synthetic resin, but also his semi-manufactured material and finished article containing the resin and having widely different composition and appearance. A number of different makers' names are also applied to substantially the same material.

Hundreds of resin-like materials have been prepared, and most of them have formed the subject matter of patents, but very few have found practical application. Academic and industrial research has been carried out from about 1890 onwards, when formaldehyde became a commercial product, and it has resulted in a most appalling mass of patent literature. Many of these specifications seem to overlap and conflict quite considerably, and it is doubtful if more than a few of them would have survived a serious legal fight.

Bayer (Ber., 1872, 5, 25, 280 and 1094) showed the possibility of producing resin-like substance from aldehydes and phenolic bodies, and Emil Fisher and Kleeberg carried this work into more hopeful channels in 1891, but brought to view nothing having commercial value. Various workers then published a variety of reactions around similar materials, using various condensing agents and, in 1899, Smith patented (E.P. 1899, 16,247) a method of making an electrical insulating material of historic interest, but of no practical importance.

The first patents of importance and the key to the possibility of commercial success are those of Blumer (E.P., 1902, 12,880) and Luft (E.P., 1902, 10,218), who both heat phenol and formaldehyde solution in presence of an acid catalyst.

Story patented (E.P. 1904, 8875), a simple and workable process using no catalyst and excess of phenol, which produced lacquers and transparent or translucent blocks for further machining.

De Laire (E.P. 1905, 15,517) produced resin-like substances from cresols, whilst the following three years saw a series of patents, involving the use of alkaline

catalysts or condensing agents and a large number of variations in material and methods, in which the names of Knoll & Co., Lebach & Stephan are prominent.

The credit for the foundation and development of the synthetic resin industry belongs to Leo. H. Baekeland, who turned laboratory experiment into controllable works processes which produced saleable articles in large quantity. (Baekeland, E.P., 1908, 1921; 1908, 1922; 1908, 21,566; 1911, 26,614; 1912, 6293; 1912, 6294; 1915, 7284.) Baekeland also eventually founded what is now the Bakelite Corporation and its subsidiary firms, which are the largest producers of phenol-aldehyde resins and their products.

Following Baekeland in America, came Redman and his associates with further modification in process, and J. W. Aylesworth with elaborate chemical explanation in his patent specifications and a distinctly new process. Patent litigation of a protracted and ruinous nature appeared to be inevitable, but these American firms eventually settled their differences by commercial combination.

The earliest manufacture of synthetic resins in Britain follows the patent of Story, but no serious commercial development occurred until 1913-1914. The growth of the industry here has been lamentably slow, although there is a potential market for at least five times the present output. The Bakelite Corporation of Great Britain, which is an American concern, has now obtained control of some English companies, and proposes to develop increased output in Britain.

Up to the year 1914 all the research of commercial value centred on phenol-aldehyde resins. Many other avenues have been searched, but only two or three promise to be of industrial use, and are mentioned later.

PHENOL-ALDEHYDE RESINS

These resins are of much the greatest commercial importance. The type is characterised by a primary or intermediate stage in which it is soluble and fusible, and can be mixed with filling, colouring or other ingredients, and a final stage in which it is substantially hard, infusible and insoluble.

A resin may be prepared by heating under a reflux condenser one molecular equivalent of crystal carbohydric acid with one molecular equivalent of 40% formaldehyde solution. After several hours the condensation is complete and the mixture separates into an upper watery layer and a lower resinous layer. Acids, alkalis and salts which act as electrolytes, catalysts, or condensing agents may be added to the mixture. They considerably shorten the time of reaction, and may produce resins having different practical use or final properties. Paraformaldehyde, hexamethylenetetramine, and other substances producing formaldehyde and catalysts may be used, while cresols sometimes replace phenol. In these cases the characteristics of the intermediate and final resins may differ considerably. In practice, synthetic resins are actually made from synthetic phenol and synthetic formaldehyde, thus making the product truly synthetic. The "treacle," "primary" or "A" resin thus produced is separated from the watery layer and dried by heating under vacuum. It is a sticky, viscous mass, either clear or

translucent, soluble in alcohol and acetone, but not in benzene or petrol. If this "treacle" is further heated under controlled conditions, it polymerises to the "resin" or "B" stage, when it has the appearance of common rosin, melts to an extremely viscous mass at temperatures below 80° C., and is still soluble in alcohol and acetone. The "treacle" and "resin" are intermediate stages which make possible the commercial production of the final and only useful stage having the shapes, colours and general properties desired.

The "final," "baked" or "C" stage is produced by still further heating and polymerisation, when it is now insoluble in alcohol and acetone and does not soften when heated. The "final" state of the various phenol-aldehyde resins may exhibit some difference in physical properties, but, generally speaking, they do not soften on heating, are not decomposed at temperatures lower than 350° C., are insoluble in all the usual organic solvents, acids, alkalis and chemical solutions, except concentrated nitric and sulphuric acids and caustic solutions. Strong caustic soda will dissolve them, and they may be reprecipitated on the addition of acid. This was proposed as a method of purification by Potter (E.P. 1919, 131,112).

When cresols are used to replace phenol the resulting final product is generally softer and more flexible. *o*-Cresol alone combines more slowly with formaldehyde, and by incomplete combination produces this softness and flexibility. Conflicting statements are made with regard to the speed of reaction and degree of combination of the three cresols with formaldehyde, due most probably to the variable composition of the commercial cresols used by the experimenters and the unobserved catalysts present.

A most important variation in method of manufacture is the two-stage Aylesworth process (E.P. 1911, 3496), in which phenol is heated with only about two thirds of the required quantity of formaldehyde and a resin formed which does not give a hard, final product on heating. This molten resin is usually dissolved in alcohol, together with a sufficient quantity of hexamethylenetetramine to supply the remainder of the formaldehyde necessary for producing a resin which hardens quickly on heating. This method is said to give a more easily controlled works process of making moulding powders.

Many variations in plant and method are in use as the result of technical experience, but the general procedure follows the outline given above.

Much has been written about the chemical constitution of the phenol-aldehyde resins and the mechanism of the reaction, but proper investigation of molecular weight and other characteristics is practically impossible with such insoluble, infusible and chemically inert final products. The simplest condensation product of phenol and formaldehyde would be *o*-oxybenzyl alcohol or saligenin, a crystalline substance which, on dehydration by heat, assisted or not by a catalyst, gives a resinous substance. The *para*-alcohol may also be formed, and combination may take place between phenol and alcohol or between the two alcohols. Condensation on these lines theoretically takes place first, followed by polymerisation, but the two processes may be proceeding at the same time in practice.

When mixed cresols are used together with phenol, the reaction is even more difficult to follow, but technical observation of the properties of the variety of resin-like bodies it is possible to make from phenol and formaldehyde leads to the conclusion that a number of reactions go on side by side. The speed of reaction is controlled by temperature, catalyst, and the proportion of free formaldehyde present, and this determines the proportion of the various compounds, or polymers, which form the final mixture. Excess of phenol in the reacting mixture apparently produces a solution of normal final product resin in the excess of phenol, and uncombined phenol is generally found in the commercial resins.

Baekeland and others have prepared crystalline compounds of phenol and cresol with hexamethylene-tetramine in excess of the mono-formaldehyde requirements. Lebach and Redman prepared hexamethylenetetramine-triphenol, which gives off ammonia and methylamine when heated, leaving an infusible final resin.

It seems safe to assume that each of the commercial phenol-aldehyde resins is a mixture of compounds, their polymers and uncombined reagents, the complexity of which depends upon the methods used by the maker. In order to reproduce batches of resin having the same physical properties, it is necessary to repeat exactly the technical details of the process used, and this involves chemical control.

PURE RESIN PRODUCTS

Final products containing over 95% of resin come into this class, the remaining ingredients being colours or other additions which produce opaque or cloudy effects. Artificial amber, which very closely resembles the natural product, is made by adding to the initial reacting mass or to the "treacle" a dye, such as auramine, and oil or wax, which emulsifies and produces the cloudy appearance. The viscous material is then heated carefully for several days at 50° to 85° C., in moulds to form blocks, rods, or other rough shapes. Excess of phenol or cresol is generally used, catalysts are absent, and the polymerisation is done slowly to avoid bubbles and obtain transparency. Phenols in excess reduce brittleness and improve machining properties. A pale straw colour is the lightest natural colour so far produced, but this can be coloured with a small amount of bright dye or pigment. These goods are not moulded by pressure, but are finished by machining the rough-cast blocks.

MOULDING COMPOSITIONS

Probably over 75% of the phenol-aldehyde resins are made into moulding powders, consisting of resin, colouring matter, and the so-called "fillers," which give strength and mechanical properties to the moulded piece. Mineral powders could be intimately ground and mixed with the synthetic resin in its "resin" or "B" state, but the moulding made from this dry mixing would lack strength, be uneven in texture, and have a high specific gravity. All kinds of filling materials have been proposed, but the only one of industrial importance is wood meal, because it is light, fibrous, absorbs the resin, and produces easily machinable mouldings.

Some moulding powders are made by masticating the "resin" or "treacle" with the dried wood meal and

colouring matters, but the best qualities are made with an alcoholic solution of the "treacle" or "resin" which, having a lower viscosity, gives better impregnation of the wood particles. Accelerators such as hexamethylenetetramine are frequently added to reduce the subsequent hardening period.

A sticky mixture is heated under very carefully regulated conditions with the object of polymerising the resin as far as is technically safe, and thus reducing the time required for hardening in the mould. It is then dry and not sticky when cooled, and is ground and packed in moisture-proof containers. The moulder requires a powder which softens thoroughly when put into the hot mould and flows easily under pressure, but at the same time bakes to its final hard state in a few minutes at a temperature of 175° C. to 190° C. To meet these requirements and reproduce the same characteristics at will, requires exact technical control in manufacture. In addition, a good powder moulded under standard conditions in a properly designed and well-polished mould should not shrink unduly, should leave the mould cleanly, and produce an article having an even colour and texture with a perfect surface finish.

MOULDED ARTICLES AND THEIR MANUFACTURE

Almost anything can be moulded with these synthetic resin compositions, and light articles of intricate shape with engraved or embossed decoration are in daily production. Metal insertions are regularly moulded solidly into magneto bodies, distributors, radio valve bases, commutators and terminal boards at the one operation, which simplifies design and assembly, improves the electrical insulation value, and reduces cost of production.

Every moulded article requires a mould which may cost from £4 for a small single-impression of simple design, to £150 for a complicated multiple mould. As a mould can only turn out a definite number per day, the number of moulds is multiplied to meet the rate of delivery required. A hard steel mould can produce many thousands of pieces before it is worn out.

The largest market is for moulded articles of a few inches in diameter required in fairly large numbers, but articles up to 2 sq. ft. are regularly made from these moulding compositions. It is technically possible to mould large tanks and other shapes, but the cost of the moulds and the size of press required to develop two or three thousand tons pressure would make the cost prohibitive unless large numbers of the same article were required.

Moulded articles can be purchased from specialist firms which provide moulds to suit their customers' requirements. Moulding powders are purchased by some large manufacturers of motor accessories and electrical apparatus who mould their own components. If tool-making facilities or press plant are available, it may pay to mould rather than purchase finished mouldings required in very large quantities.

Process.—The quality of the moulding powder is important, but correct mould design, temperature, time and pressure are equally important in the production of sound goods. The operation of moulding consists of assembling the hot mould, adding the correct

weight of moulding powder, replacing the piston, placing in the heated press and applying a pressure of 1000 to 3000 lb. per sq. in. of moulded piece and heating for a suitable time at a temperature of 175° to 190° C., and then removing from the press and ejecting the hard moulding from the mould. The range of temperature when moulding carbamide resins is much narrower and lower.

For small moulds and thin goods, the whole operation is complete within 5 min., but heavy moulds and

circulation before removing the pressure, or to cool under pressure in a second press.

Moulds.—The volume of the powders is two or three times the volume of the finished article, and allowance

FIG. 1
Positive Mould

thick mouldings require longer time to attain the necessary temperature. Excessive temperature and time cost money, but are not generally harmful. They may cause pre-hardening and flow marks if they occur before the pressure is applied, or undue shrinkage of the piece or damage to a fugitive colouring matter. The appropriate pressure is determined by the plasticity, speed of hardening and adhesiveness of the moulding

FIG. 2
Positive Flash Mould

powder, and the intricacy of the mould or presence of delicate metal insertions.

Powders which have been exposed to the air and become damp, or powders containing excess of "hexa" or similar additions, give off vapour or gas when heated. If the pressure is removed from such powders at a high temperature, especially with an under-baked and slightly soft moulding, the vapour will produce blisters in the goods. To remedy this, it is the practice in some works partly to cool the press and moulds by a water

FIG. 3
Open Flash Mould

for this has to be made in designing the moulds, which are of three main types: (a) the positive or piston mould, where the powder is compressed in a closed vessel with the full applied pressure resting on the article (Fig. 1); (b) the positive flash type, in which any excess powder forms a fin or flash on which the piston also presses, but which is retained within the closed mould

FIG. 4
Three-platen press with moulds in position. The press has one single action valve fitted with high- and low-pressure hydraulic supply. Platens fitted for steam heating and water cooling.

(Fig. 2); and (c) "open flash" or "spew" moulds out of which the excess material has free escape until the upper half rests on the lower (Fig. 3). This last type is only used when the powder is first compressed cold to a hard tablet or briquette which slightly more than fills the mould. It is obvious that the moulding cannot be so thoroughly compressed as in a positive mould, and this type has limited applications.

A large number of small articles may be moulded in one operation on a multiple-mould, and if this is used in a semi-automatic press the two halves of the mould would be fixed to the press and may contain their own heating arrangements. Multiple ejector pins are attached to an independent ejector ram of the press. The moulds may be made of any material which will withstand the temperature and pressure and take a very high polish. We are practically limited to close-grained hard steels or case-hardened steels which will take a mirror finish on those parts in contact with the moulding powder. As an accuracy of size to 0.002 in. is frequently called for in engineering component moulding, after allowing for contraction, it is obvious that the mould has to be made by a skilled tool maker and finally polished by special methods.

Presses.—Quickly acting hydraulic presses are necessary for economic production and they are generally fitted with steam-heated platens. A simple single-ram press is illustrated which takes three moulds and develops 20 tons pressure. It is fitted with high and low-pressure hydraulic service, steam heating and water cooling service to the four platens by flexible pipe connexions behind, and has unusually large space between platens to accommodate specially deep moulds. A battery of single deck presses of the same type operated by quick-acting valves, arranged so that the hot moulds can be pushed along metal benches to another cold press which ejects piston and moulded piece, is often more convenient for quick production from hand-assembled moulds. While one mould is discharging and re-charging, a second mould is under the press.

(To be continued.)

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

EXTENSION OF PERIOD FOR REDUCED RAILWAY FARES

Since the programme for the Annual Meeting was printed, the Railway Companies of Great Britain which agreed to issue tickets at the ordinary single fare and one third for the double journey to persons travelling to Edinburgh to attend the meeting have extended the validity of these tickets, and they will be available from Saturday, July 2, to Monday, July 11. These tickets will be obtainable at the time of booking on production of vouchers which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

It is urgently requested that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

If the holder of a return ticket at the reduced fare wishes to make use of it after the period for which it is available has expired, the excess payable will be the difference between the fare paid and the fare payable for an ordinary return or a tourist ticket, where such is available. This excess would have to be paid at an Edinburgh booking-office before commencing the return journey.

PROPOSED EXCURSION TO ST. ANDREWS ON SATURDAY, JULY 9

The train will leave the Waverley Station, Edinburgh, at 9.30 a.m., arriving at St. Andrews at 11.22 a.m.

A visit to the University, including the Chemical Laboratories, will be arranged for the afternoon, and the St. Andrews University Court has kindly offered to entertain the members to tea in the University Buildings.

The return train will leave St. Andrews at 5.35 p.m., arriving in Edinburgh at 7.26 p.m.

Members will also have an opportunity of visiting other places of historic interest in St. Andrews or of playing golf.

CHEMICAL ENGINEERING GROUP

A lunch for Members of the Chemical Engineering Group and their guests is being arranged for Wednesday, July 6, at 12.30 p.m., immediately after the meeting of the Group. The lunch will be held in the University Union, Park Place, Edinburgh. Price of tickets 5s., exclusive of wine and gratuities.

Members of the Society who are not Members of the Group are welcome to attend the lunch.

Charabancs will call at the University Union at 1.55 p.m. for those going to the Gasworks, and at 2.5 p.m. for those proceeding to King's Buildings.

Application for tickets should be made immediately to the Secretary of the Group, Abbey House, Victoria Street, London, S.W.1. After July 1 communications regarding the lunch should be addressed to Dr. W. T. H. Williamson at the North British Station Hotel, Edinburgh.

BUREAU OF CHEMICAL ABSTRACTS

The following are the prices at which copies of the Index to British Chemical Abstracts, 1926, can be purchased:—

By members of the Chemical Society or the Society of Chemical Industry—5s. post free; by subscribers—10s. post free.

DEATHS

Clark, John (elected 1900), of Broadway Works, Millwall Docks, London, E.14, Manufacturing Chemist. On June 5, 1927.

Kerr, Samuel T. (elected 1890), of Delaware Avenue, and Spring Garden Street, Philadelphia, Pa., U.S.A., Salt Manufacturer. On January 31, 1927.

Van Laer, Norbert (elected 1896), of 18, Laurence Pountney Hill, Cannon Street, London, E.C.4, Brewer and Chemist. On May 28, 1927.

Wesener, Dr. John A. (elected 1903), of 31, North State Street, Chicago, Ill., U.S.A., Consulting Chemist. On November 17, 1926.

Williams, W. Carleton (elected 1884), of Broomsgrove, Goring-on-Thames, Professor of Chemistry. On May 25, 1927.

AMERICAN SECTION

The May meeting of the American Section of the Society of Chemical Industry was held on Friday evening, May 6, 1927, in Rumford Hall of the Chemists' Club, Dr. Redman in the chair. The secretary announced the meeting of the Canadian Convention of Chemists at Quebec from June 6-9, and the Society's annual general meeting at Edinburgh from July 4-9. The election of officers was announced as follows:—

Chairman, Dr. L. V. Redman; *Secretary*, Dr. F. D. Snell; *Treasurer*, Mr. F. C. R. Hemingway; *Members of the Executive Committee*, Dr. James Kendall, Mr. Irving Hochstetter, Dr. Herbert R. Moody, and Dr. D. D. Jackson.

Mr. Paul Mahler, after defining a consultant, discussed the problems of the activated carbon industry in a very interesting manner. He classified the subject into manufacture, evaluation, uses and methods of application, and revivification.

Manufacture was covered hurriedly in a few words. Evaluation was taken up in detail and discussed in terms of absorption as measured by the Hess-Ives tintophotometer. Every problem of decolorisation must be studied individually, and careful data kept in order to make the proper recommendations. Application was discussed with, in particular, a case of decolorising and cleaning dry cleaners solvent. Time did not permit an extensive discussion of revivification. The paper will appear in CHEMISTRY AND INDUSTRY at an early date.

Mr. Lewis, of the L. Martin Company, described the production of carbon black and lamp black. He gave details of various methods of manufacture and reasons for the migratory nature of the industry. Interesting slides were shown of the agglomeration and dispersion of short and long blacks ground in oil. Explanations were given of the apparently different colour of dispersions of carbon black and lamp black and of their varied applications.

Seventy-five members and guests attended the dinner in the Club dining-room at 7 p.m. preceding the meeting. About 200 attended the meeting, which closed at 10.30 p.m.

CALENDAR OF FORTHCOMING EVENTS

- June 29. ROYAL SOCIETY OF ARTS, John Street, Adelphi, W.C.2., at 4 p.m. Annual General Meeting.
- July 4 to 9. SOCIETY OF CHEMICAL INDUSTRY. Forty-sixth Annual Meeting in Edinburgh. (See CHEM. AND IND., May 20, 1927, p. 404.)
- July 4 to 8. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual Meeting in Edinburgh. "Some aspects of the manufacture of fibrous cellulose," by Dr. J. L. A. Macdonald. A discussion will follow.
- July 15 & 16. INSTITUTION OF SANITARY ENGINEERS. Annual General Meeting and visits in Birmingham.
- Aug. 20. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, Newcastle-upon-Tyne. Annual Meeting at 2.30 p.m.
- Aug. 31 to Sept. 7. BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Annual Meeting (97th year) at Leeds.

INTERNATIONAL OIL, CHEMICAL AND COLOUR TRADES EXHIBITION

We are informed that a meeting of the exhibitors of this exhibition was held at the Royal Agricultural Hall on Friday, June 17, at the request of the organisers; that the speeches were eulogistic as regards the success of the exhibition, and it was unanimously decided that the exhibition should be repeated in the spring of 1929, and that the following gentlemen from those present were elected by the exhibitors to serve as an Honorary Advisory Committee for the next exhibition:—Mr. S. J. C. Mason (Messrs. Bush, Beach & Gent), Mr. F. Burrell (J. W. & T. A. Smith, Ltd.), Major J. H. Foster (Joseph Foster & Sons), Mr. J. R. Torrance (Torrance & Sons), Mr. W. Gundry (Morris Ashby, Ltd.), Mr. S. W. Whiffen (Whiffen & Sons), Mr. L. H. Hill ("Chemical Engineering Catalogue"), Col. A. E. G. MacCallum (Sidney Smith & Blyth, Ltd.), Mr. F. Gunn (W. T. Nicholson & Clipper), Mr. F. J. Ryland (M. Lummerzheim et Cie), and Mr. K. L. Cobb (The Building and Metal Export Co.). The hope was expressed that a representative from Messrs. Howards & Sons, Ltd., would join.

CANADIAN METALLURGICAL NEWS

A decision of considerable interest was recently rendered by Justice Audette, of the Exchequer Court of Canada, in an action brought by the Electrolytic Zinc Process Co. (a Montana corporation and subsidiary of the Consolidated Mining and Smelting Co., Ltd.) for a declaration that the alleged patent of the French Electrolytic Zinc Process Co. was invalid, because of prior art and other grounds. Judgment was given cancelling the alleged French patent. The originator of the alleged patent was Andrew G. French, metallurgist, reputed to have made important discoveries in connexion with ore reduction which were said to have been put to use in Swansea, Wales, and later with experience at Broken Hill, in Australia. A company was formed at Nelson, B.C., about 1911 or 1912. Both Dominion and British Columbia Governments made grants to the French company. The latter had a plant at Fairview, B.C., and the Consolidated Company also lent facilities at Trail, which were occupied for several months. The inventor died, and was succeeded by his son, Thomas French. The Consolidated Company took an option on the French process, but did not purchase it, as it developed its own process, which is used on the Sullivan and Slocan ores. After the war the French plant was closed down. In 1924 the French company instituted proceedings against the Consolidated Company in the Quebec courts (Montreal head office of the Consolidated) for alleged infringement of a Canadian patent covering the production of electrolytic zinc, and maintaining that the process was the financial salvation of the defendant company. The claim was for \$8,000,000. The defendant company immediately brought suit for declaration of the invalidity of French's patent. After a hearing of over two months the decision, already mentioned, was given.

The old lead and zinc mines in Dorion township, 35 miles east of Port Arthur, Ont., are being re-opened, while the old Omega mine, in the same district, is shipping high-grade lead ore.

[To supplement the notice of Col. Pollitt, which appeared in our columns last week¹, we here publish his portrait

COL. G. P. POLLITT, D.S.O., Ph.D., Etc.

Awarded the Society of Chemical Industry's Medal, 1927

CHEMICAL SOCIETY

Twenty-two new Fellows were elected by ballot at the last meeting of the session, held on June 16, the President, Prof. H. Brereton Baker, C.B.E., F.R.S., occupying the chair. The President announced that Prof. Willstätter's lecture, entitled "Problems and methods in enzyme research," would shortly be issued in separate form, price 1s., obtainable from the Assistant Secretary. Fellows applying before Christmas Day, 1927, could obtain the Annual Reports for 1927 for 5s. 6d., post free; by applying (with remittance) before that date they could also obtain copies of the A abstracts, 1927, printed on one side of the paper only, gummed or ungummed, for £1.

The President, announcing that the Council and Fellows desired to convey, in a tangible form, an expression of their appreciation of the services of the Assistant Secretary, Mr. S. E. Carr, during the past 25 years, said that Mr. Carr's unvarying and unfailing courtesy was a great asset to the Society. Dr. Alexander Scott, who was Honorary Secretary at the time of Mr. Carr's appointment, testified to his valuable and unstinted services over a period during which so many changes in the Honorary Officers had taken place. The President then handed Mr. Carr cheques, being gifts from the Society and from the Fellows, who also presented him with a "grandmother" clock and an illuminated album containing the signatures of the subscribers.

Mr. Carr, who expressed his astonishment, as well as his appreciation of, and gratitude for the gifts, thanked the Council and Fellows for the goodwill which had prompted their action. He had been fortunate in the happy relationship which had always subsisted between the Honorary Officers and himself.

Mr. I. Vogel then read the following paper:—

Syntheses of cyclic compounds. Part I. Ethyl $\beta\gamma$ -dimethylbutane- $\alpha\alpha\delta\delta$ -tetracarboxylate and some cyclobutane compounds derived therefrom.

REDUCTION of ethyl ethyldenemalonate with moist aluminium amalgam yields ethyl $\beta\gamma$ -dimethylbutane- $\alpha\alpha\delta\delta$ -tetracarboxylate, which on hydrolysis with alcoholic potash gives the two corresponding stereo-isomeric tetracarboxylic acids. When heated at 200°, this yields the $\beta\beta'$ -dimethyladipic acids. Treatment of ethyl $\beta\gamma$ -dimethylbutane- $\alpha\alpha\delta\delta$ -tetracarboxylate with sodium methoxide and bromine gives the cyclobutane compound, which on hydrolysis and heating to 180° affords the two stereo-isomeric $\beta\gamma$ -dimethylcyclobutane- $\alpha\delta$ -dicarboxylic acids (I) and (II).

The *cis* acid (I) yielded an anhydride with acetyl chloride, while the *trans* acid (II) yielded the *cis* anhydride with acetic anhydride.

The bearing of these results on the modified strain theory of Profs. Thorpe and Ingold is discussed.

Prof. J. F. Thorpe referred to the bearing of investigations on the four-membered ring on the elucidation of the structure of pinene.

In reply to Prof. C. S. Gibson, who asked whether the stereoisomerism of the four-carbon acids had been considered, Mr. Vogel said that the matter would be investigated when a series of the compounds had been prepared.

Mr. B. Cavanagh described:—

A new method of (absolute) potentiometric titration.

A NEW and very simple method of "absolute" potentiometric titration, based on an application of Helmholtz's "concentration cell without liquid junction" is described. The requisite procedure in the titration of a strong acid, chloride, bromide, and iodide, is indicated. The sensitivity and accuracy are the highest attainable by electrometric methods.

A silver halide electrode and a platinum electrode dipping into a solution containing the corresponding halide ion, hydrogen ion, and a trace of quinhydrone, develop an *E.M.F.* given by $E = E_0 + (RT/F) \log_e C_H \cdot C_X$, depending therefore at a given temperature on the product of the concentrations of hydrogen and halide ion. The whole procedure follows from this, the values (and temperature coefficients) of E_0 for chloride, bromide, and iodide having been determined.

Mr. M. P. Applebey asked how the silver halide electrode was prepared, how permanent it is, and exactly what degree of accuracy was attainable in the titration of a weak acid.

Dr. E. K. Rideal asked whether the process was intended to be an instrument of precision or a routine method: what, for instance, was the accuracy in the titration of cupric chloride and hydrochloric acid with sodium hydroxide. He had found that with a mixture of acids and salts and small quantities of quinhydrone the errors are large.

The author replied that the electrode was prepared by electrolysis of silver wire in dilute halide solutions for 1 hr. at 4–5 milliamperes; it could be kept in boiled-out distilled water for a week. In the presence of sodium or potassium chloride (or iodide) a very high degree of accuracy was attainable, the *E.M.F.* being within 0.5 (or 2–3) millivolts of that calculated. The method depended on the attainment of a particular potential, and not on the rate of change of the potential.

Dr. G. M. Bennett discussed the two following investigations:—

Cis-trans Isomerism of Disulphoxides. [With E. V. Bell.]

THE existence of optically active compounds of the type $RR'S \cdot O$ proves that in these compounds the oxygen atom is not in the same plane with the group $RR'S$, and implies the possibility of *cis-trans* isomerism in substances containing this group twice in the same molecule. A re-examination of the disulphoxide of 1:4-dithian (Crafts, *Annalen*, 1862, 124, 110) has revealed that 11% of an isomeride is present with it in the crude oxidation product.

Dithiandisulphoxide (described by Crafts), decomp. 263° , is monoclinic. The *disulphoxide*, decomp. $235-250^{\circ}$, is anorthic, and is 5 times as soluble in 90% alcohol as its isomeride. A complete crystallographic description of each is given.

The disulphide, $\text{CH}_3(\text{SMe})\cdot\text{CH}_2\cdot\text{SMe}$, also yields two isomeric disulphoxides on oxidation, *dimethylethylene-disulphoxide*, m.p. $163-164^{\circ}$, and the *disulphoxide*, m.p. $128-130^{\circ}$, which is the more soluble in various solvents.

Decomposition of some Halogenated Sulphides, and the Nature of the "Polymeric" Ethylene Sulphides.
[With E. V. Bell and A. L. Hock.]

$\gamma\gamma'$ -DI-IODODIPROPYL sulphide decomposes when kept with liberation of trimethylene di-iodide. $\beta\beta'$ -Dichlorodiethyl sulphide is reversibly decomposed at 180° into dithian and ethylene dichloride, and the same reaction occurs more slowly at the ordinary temperature. These observations, the decomposition of a δ -bromo-sulphide recently described (J., 1927, 477) and certain anomalies recorded in the literature are explained as similar processes involving the formation of sulphonium salts and their dissociation into other components. The changes for dichlorodiethyl sulphide, for instance, are as follows:—

The "depolymerisation" of some of the "polymeric" ethylene sulphides is to be attributed to the same type of change, and depends on the presence of a small proportion of halogen in these substances. "Polymerides" free from halogen will not yield dithian when heated, but it is now found that they yield dithian when heated in presence of hydrogen bromide. This supports the views previously expressed as to the nature of these "polymerides" (Nature, 1926, 118, 555).

Dr. H. Phillips asked whether the author was satisfied regarding the chemical nature of the disulphoxides, the tendency being for both oxygen atoms to become attached to the same sulphur atom.

Dr. Bennett replied that the behaviour of the compounds with hydrochloric acid at 100° , and with zinc dust and hydrochloric acid, was convincing evidence that they were disulphoxides, but he would also examine their reaction with bromine.

ELECTROPLATERS' AND DEPOSITORS' TECHNICAL SOCIETY

The 18th ordinary meeting of the Society was held on Wednesday, June 15, at the Northampton Polytechnic Institute, when Mr. E. Downs, M.Sc., read a paper on "Electrolytic refining." Mr. W. A. C. Newman occupied the Chair.

Mr. Downs said that of the three methods available for refining silver, viz., the metallurgical, chemical and electrolytic, the last was finding increasing favour on account of the relative ease with which it was possible to obtain a high purity product. The purity could be as high as 99.98%.

The earliest attempts at silver refining were made by Wohlwill in 1873, using an acid sulphate solution. This was abandoned in favour of the Moebius process introduced in 1884, which with only slight modifications is used at the present time. The electrolyte consists of copper and silver nitrates and nitric acid. The material usually refined consisted of *dore* silver, having a very high silver content; gold and silver alloys from various sources, e.g., jeweller's residue and scrap composed of 2-30% gold, 60-90% silver and 15-20% copper and base metals; and silver and copper alloys used for coinage and in the jewellery trade containing 70-92½% silver. The main impurities comprised lead bismuth, platinum metals, tellurium, selenium and zinc. The impurities which are insoluble remain in the anode slimes or may be precipitated at the anode as basic compounds, e.g., lead peroxide; silver occurs as the oxy-nitrate compound and to a lesser extent copper. To prevent the solution of bismuth and tellurium, the solution must be kept neutral.

Copper being nearest to silver in the electrochemical series has the greatest tendency to co-deposit with the silver. To ensure that this shall not occur, the solution is kept rich in silver ions, and the copper ion concentration kept within limits by periodic withdrawal of the electrolyte addition of silver solution and efficient circulation of the electrolyte is ensured to prevent polarisation.

The two cells in general use, the Moebius or vertical cell and the Balbach or horizontal cell were then described and compared. The current efficiency in both types reaches 95%. The voltage required in the Balbach is twice as great as in the Moebius owing to the greater distance between the electrodes in the former case and also the added resistance of the anode slimes.

There is, however, very little difference in the cost of working.

Mr. D. McDonald, in opening the discussion, said that electrolysis was undoubtedly the best method for silver refining not only on account of the purity of the product, but also because of the completeness of the recovery. The chief source of refinable material was not now the ore but the by-products of the electrolytic industries, e.g., those producing lead and zinc. The physical nature of the product presented an interesting field for research—it varied so. Nitrites possibly have a similar effect to selenium. Again, the anode slimes would be worth investigation—their constitution was little known. How was it, too, that finely divided silver found its way into the deposit?

Mr. McNaughton referred to the hardness of the deposit, and wished to know whether the hardness number had been determined. It would be interesting if this could be linked up with the hardness of electro-deposited nickel and chromium. An increase of temperature would be expected to give a soft deposit. He also wished to know what type of pump had been used, and whether there was any trouble with the anode slimes in pumping.

Mr. Perring asked whether the cells were arranged in parallel or series, and what was the maximum voltage used?

Mr. Ollard wished to know whether an arrangement for incorporating a moving cathode could not be utilised. He gave details of a revolving disc cathode from which the deposit could be scraped off.

Mr. Hothersall gave his experience in dealing with anode slimes, and wished to know if filtration had been used.

Mr. Gardam asked if mercury present as an amalgam would not be troublesome. He said that the electrolytic process had completely replaced smelting in some cases, and that in one case the chain from the ore to the finished product was entirely electrochemical.

Mr. Wernick said it was somewhat surprising to find that colloids had not been used until latterly in order to reduce the crystal size of the deposit. He asked for the relative purity of the product and the costs in the three processes available.

The Chairman then gave some very interesting information of the Cleave Refining Process which he had carried out at Ottawa, where a very high output had been achieved.

Mr. Downs then replied to the discussion, and was accorded a hearty vote of thanks.

Copies of the paper may be obtained from the acting Hon. Sec., 3, Bridge Street, London, E.3, and also particulars of membership of the Society.

The next meeting of the Society will open the new Session in October next.

CORRESPONDENCE

VERBIAGE?

SIR,—The remarks made by Prof. Armstrong in his letter to you regarding his prophecy bespeak a great deal in keeping with the theories of Einstein and Relativity. The old idea of fixed bodies or characteristics like that of fixed stars is in the light of modern reason untenable. If a list of compounds be drawn up showing increase in acidity and decrease in basicity there is no middle to that list. There is no absolutely neutral compound thereon. A compound is only more acid than another according to its behaviour with an indicator, and water is only neutral as far as such can make manifest to our eyes. I have in the *Chemical News* taken water as an acid, and called it Hydric Acid, for it makes more hydrates in its reactions with salts than hydrochloric acid makes chlorides. There is a great list of metals which I have christened the "Milky Way" from the ease with which their chlorides hydrolyse with water, especially in Group III including the rare earths, and produce the hydrate. I have represented water as

$\text{H}:\text{OH}$, the hydrogen salt of hydroxyl. In electrolysis I have found it acting like any other acid, practically always producing the hydrate. No acid will act as an acid without it, and there is overwhelmingly more reason to consider it as an acid than such bodies as sulphuretted hydrogen, or say carbonic or silicic acid, which it fights successfully even with insoluble salts like those of lead, producing basic salts.

Yours faithfully,

ROBERT SAXON

Baldon, Yorks

PERSONAL AND OTHER ITEMS

Among the distinguished foreign visitors to the Society's Annual Meeting at Edinburgh will be M. Agache, the president of the Société de Chimie Industrielle, and Prof. Dr. K. M. Meyer, vice-president of the German Chemical Society and a director of the I.-G. Farb. Gesellschaft.

Dr. Leonard James Spencer, F.R.S., has been appointed a deputy keeper in the Department of Mineralogy of the British Museum.

The University of Manchester has appointed Mr. G. G. Hepburn, B.Sc., Ph.D., special lecturer in chemical technology.

Dr. George Harker has resigned from his post as Lecturer in Organic Chemistry at the University of Sydney, and has become a partner in the firm of Messrs. Campbell & Harker, Consulting and Analytical Chemists, of 35-43, William Street, Melbourne.

Institute of Chemistry

The following have passed the examination for the Associateship in General Chemistry of the Institute of Chemistry:—(1. Brown, A.H.-W.C., D. M. Freeland, G. Harding, E. C. Keeley, B.Sc., C. D. Lawrence, B.Sc., D. T. Lucke, B.Sc., E. F. Natrass, B.Sc., A. W. Thompson, S. L. Tompsett, B.Sc. The following have passed the examination for the Fellowship in Branch A:—Inorganic Chemistry, Section II, Metallurgy:—H. N. Blyth, B.A., and J. Sandilands. In Branch D: Agricultural Chemistry:—E. R. Ling, B.Sc., A.R.C.S. In Branch E: The Chemistry (including Microscopy) of Food and Drugs, and of Water:—H. Childs, B.Sc., C. Chilvers, B.Sc., R. Crosbie-Oates, B.Sc., F. P. Hornby, B.Sc., A. S. Houghton, M.Sc., T. Mann, H. E. Monk, B.Sc., J. G. Sherratt, B.Sc.Tech., R. W. Sutton, B.Sc. Tech., and R. W. Watridge, B.Sc. In Branch F: Biochemistry, with special reference to Chemical Pathology:—F. D. M. Hocking, M.B., B.S., M.R.C.S., L.R.C.P., A.C., G.F.C. In Branch G: Industrial Chemistry, with special reference to Coal Tar and Ammonia:—R. G. W. Eadie, B.Sc. In a Special Examination in the Chemistry of Foods, with special reference to Milk and Milk Products:—M. Bogod, A.R.C.S. In a Special Examination in Oils and Fats:—W. Rhys-Davies.

Dye Industry in Japan

There is very little business to be done in dyestuffs in Japan at present, and no improvement in the textile industry is yet in sight.

The Japanese Department of Commerce has issued

regulations to prohibit the falsification of the dye labels and packages, and thus prevent the sale of Japanese dyes under foreign labels.

Artificial Silk in Germany

A new artificial silk company, with a capital of £600,000, has been established at Breslau to take over and extend the artificial silk factory at Cawallen, near Breslau, belonging to the Giesche Mining Co., of Breslau. The founders are the Giesche Mining Co., the Vereinigte Glanzstoff Fabriken Co., of Elberfeld, and the N.V. Dutch Art-silk Co., of Arnheim, the Board of the Disconto Bank of Berlin, and the J. Frank and Co. banking house of Crefeld. The Vereinigte Glanzstoff and the Dutch Art-silk Co. will place at the disposal of the new company all patents, procedure and experience, and will support it in all technical and commercial matters. The products of the new undertaking will be sold through the sales organisation of the Vereinigte Glanzstoff Fabriken, which, together with the Dutch firm, will receive some £200,000 shares out of a future capital increase.

Belgian and Czechoslovak Uranium Pigments

An agreement has been made by the Belgian company which produces radium and uranium colours at Oomen and the State factory at Joachimsthal in Czechoslovakia for a joint sales organisation for uranium pigments with headquarters at Cologne. As the United States production is said to be falling off, this announcement is of particular interest.

The Norwegian Carbide Industry

Of the various branches of the Norwegian electrochemical industry, the carbide industry is one of the oldest, having been established nearly half a century ago. Its rapid development is largely attributable to the abundant cheap supply of hydro-electric power and the close proximity to England, the chief market for carbide. At present there are about a half-dozen carbide works in Norway, with an approximate yearly capacity of 100,000 tons. The most important are the plants at Odda, Meraker and Hafsland, which have a joint management. Approximately one third of the carbide production of the Norwegian industry is exported. The bulk goes to England, but Norwegian carbide during late years has also found its way into practically all the important world markets. The remaining two thirds of the domestic production is consumed mainly in the manufacture of fertilisers, of which large quantities are exported. The exports of calcium carbide during 1925 declined to 29,478 metric tons from 33,491 tons in 1924.

Sodium and Boron Compounds in the U.S. in 1926

The production of sodium compounds, not including common salt, from natural salines and brines in the United States in 1926, as indicated by sales or shipments by producers, amounted to 93,480 short tons, valued at \$2,326,750, according to the U.S. Bureau of Mines. These figures show an increase of 28% in quantity and 11% in value as compared with 1925. They cover the output of sodium carbonate, sodium bicarbonate, sodium sulphate, trona and sodium borate (borax). The total sales of sodium carbonates in 1926 amounted to 56,750 tons (\$1,154,840), an increase of 24% in

quantity and 25% in value. The sales of sodium sulphate in 1926, comprising natural salt cake and Glauber's salt, were 19,620 tons (\$166,800), about double the output of 1925. The boron minerals shipped in 1926 amounted to 115,970 tons, an increase of 2%. The value was \$3,128,110. The boron minerals included borax and calcium borate (colemanite).

Winter Oilseeds Crop of British India, 1926-27

From information received from reports of provinces and states which contain 94% of the total area in India under rape and mustard and 93% of the total area under linseed, the total area under rape and mustard amounts to 5,491,000 acres, or 1% below that of last year, and the total area returned for linseed is 3,348,000 acres, or 7% below the last year's figure. The total estimated yield of rape and mustard is 983,000 tons, as against 909,000 tons, or an increase of 8%. The total estimated yield of linseed is 407,000 tons, compared with 402,000 tons last year, an increase of 1%. The condition of the crops is, on the whole, fair.

Sesamum Crop of British India

The total area reported to be under sesamum crop in provinces and states which contain, on the average, 89% of the total area sown in India, is estimated at 4,533,000 acres, as against 4,684,000 acres last year, a decrease of 3%. The total yield is estimated at 358,000 tons (excluding Hyderabad, for which no quantitative estimate of outturn is made at present), as against 364,000 tons last year, showing a decrease of 2%. The weather is not very favourable, but the condition of the crop, on the whole, is reported to be fair.

Groundnut Crop of British India, 1926-27

From information based on reports from provinces which contain 93% of the total area under groundnut in India, the estimated acreage is 4,163,000 as compared with 3,973,000 acres in 1925-26, an increase of 5%. The total yield is estimated at 1,931,000 tons of nuts in shell, as against 1,999,000 tons last year, a decrease of 3%. The condition of the crop is reported to be fairly good.

Sugarcane Crop of British India, 1926-27.

From provinces and states containing on the average 95% of the total area under sugarcane cultivation in India, it is reported that the estimated area sown is 2,920,000 acres, as against 2,679,000 acres last year, an increase of 9%. The total yield of raw sugar is estimated at 3,208,000 tons, as compared with 2,977,000 tons last year, an increase of 8%. The weather was generally favourable, and the condition of the crop on the whole is reported to be good.

Brown-coal Products in Germany

Some 110,000 to 140,000 metric tons of brown-coal tar is produced annually in Germany, the output of brown coal being 135,000,000 metric tons, compared with 87,000,000 tons in 1913. About 50,000-60,000 of the output of tar is produced in Central German lignite distillation plants, mainly by the Deutsche Erdoel A.-G. Certain amounts of gasoline substitutes are recovered from the treatment of lignite, the total output of "petroliferous products" in 1924 being 14,000 tons from shale and gas, 60,000 tons from lignite tar, and 310,000 tons from black-coal tar, exclusive of benzol.

REVIEWS

ANCIENT EGYPTIAN MATERIALS. By A. LUCAS, O.B.E.
Pp. viii + 242. London: Edward Arnold & Co.,
1926. Price 7s. 6d.

Mr. Lucas, who is the chemist to the Egyptian Department of Antiquities, has made a valuable addition to our knowledge of ancient materials in his new work. It is not generally recognised that such materials have been often daringly identified after insufficient examination and not a few misconceptions will be cleared away by the author's judicious presentation of the evidence, to which he himself has largely contributed.

The story is set in perspective by the opening outline of Egyptian history and then, in separate chapters, the origin, preparation, uses, identification, and so on, of ancient Egyptian materials are discussed. The subjects dealt with are:—building materials; faience, glass and pottery; metals; mummification materials; oils, fats and waxes; pigments and varnishes; precious stones, monumental stones; textile fabrics, leather and dyes; writing and various other materials.

Such a book appeals, not only to the archaeologist, but to all who are interested in the origins of industrial products or of art. The book is interestingly written, and invites quotation and discussion. But the space available is limited and the best thing to do is to send all who are interested in the origins of materials to the book itself; they will not be disappointed. The book is well produced and reasonably priced.

PYROXYLIN ENAMELS AND LACQUERS: THEIR RAW MATERIALS, MANUFACTURE AND APPLICATION. By S. P. WILSON, M.A., Ph.D. Second printing. Pp. x + 212. London: Constable & Co., Ltd., 1926. Price 18s.

The author of this book has had considerable experience in the manufacture of pyroxylin enamels and lacquers and writes with authority on his subject. An interesting account of the history of the cellulose varnish industry opens the first part of the book, followed by chapters in which the manufacture and properties of pyroxylin, and the various solvents (alcohols, esters, ketones), non-solvents, plasticisers, gums and resins, pigments and dyes which are employed as raw material, are discussed.

The second part of the book deals with the manufacture of pyroxylin products such as bronzing liquids, dopes for leather and aeroplanes, cements, collodion, metal and wood lacquers, lacquer enamels, passing on to discuss methods of application and miscellaneous methods of analysis, concluding with a short bibliography and a condensed index.

The point throughout is that of the manufacturer, and the author continually treads on the solid ground of experience. Numerous recipes are given to illustrate the many varieties of pyroxylin varnishes and there are illustrations of American plant used in the industry. The book will be read with interest by all those concerned with these at-times-disconcerting products of cellulose.

PARLIAMENTARY NEWS

Raw Copper Supplies

In reply to various questions, Sir P. Cunliffe-Lister said he was aware that a large proportion of the producers of copper in the United States had formed a company to regulate the sale of raw copper outside that country, and that important European interests were also parties to the arrangement. Since the formation of the company, the prices quoted to British consumers had frequently been higher than the equivalents of the prices quoted to American consumers. It was of great importance that British users of copper should be able to obtain supplies on terms as favourable as those given to their competitors, and he should welcome the development of copper production and refining within the Empire.—June 14.

Packing and Wrapping Paper (Imports)

In a written answer to Mr. Livingstone, Mr. A. M. Samuel stated that the following figures showed the total quantities of packing and wrapping paper imported into Great Britain and Northern Ireland in each of the last three years: In 1924, 4,145,463 cwt.; in 1925, 4,392,981 cwt.; and in 1926, 3,823,084 cwt.—June 15.

Iron and Steel Trade

Mr. A. M. Samuel informed Mr. Couper that he knew pig-iron was at present being sold and delivered at steel works in Lanarkshire and Glasgow district from the Continent at 72s. 6d. per ton, while the same class of pig-iron at the blast furnaces in Scotland was 76s. to 77s. 6d. per ton, exclusive of railway carriage to steel works. Continental steel plates were also being delivered at the shipyards and works on the Clyde at 145s. to 152s. 6d. per ton, as against 162s. 6d. to 167s. 6d. per ton from Scottish steel works, and steel bars were being delivered at 103s. 6d. per ton from the Continent as against 150s. per ton from the local works. These figures were substantially correct, but might not relate to identical classes of material. He was not aware of any direct subsidies by Governments on the Continent to the industries concerned. As regarded exports and imports, in May, 1927, this country imported 356,000 tons of iron and steel, and exported 422,000 tons. He considered that one of the big factors in the difference in cost in England was lower wages and longer hours on the Continent; also indirect subsidies which could not be traced in the form of low rates of interest granted to the industry; the fluctuations of the franc, rebates to producers of pig-iron for export houses, and possibly a certain amount of rebate advantage given by foreign railways for export iron and steel.—June 20.

COMPANY NEWS

BLEACHERS' ASSOCIATION, LTD.

The twenty-eighth ordinary general meeting was held on June 17, Sir Alan J. Sykes, Bart., presiding. Reference was made to the great loss incurred during the year by the death of two of the oldest directors, Mr. Warburton and Mr. Fred Whowell, and also of Mr. J. J. Kirkpatrick, who managed the Belfast branch of Kirkpatrick Bros. After briefly reviewing the accounts (cf. *CHEM. AND IND.*, June 10, 1927, p. 536), the chairman said the drop in the profits was attributed largely to the coal stoppage. It

was estimated that the total extra amount paid for coal over and above the ordinary contract price was £230,000, and, in addition, there was a loss of £200,000 due to the shortage of cloth arising from this and other causes. During 1926 there was a continual drop in the price of raw cotton; so far this year, this process had been reversed, and buyers all over the world for the first time were experiencing the benefit of rising values. Referring to the rapid growth of artificial silk production and its influence on the Lancashire trade, the chairman said the directors, alive to these developments from the outset, had maintained a keen interest throughout, and by the carrying out of countless experiments, the introduction of new plant, and the modification of existing machinery, the Association was in an extremely favourable position to process, with the highest degree of technical efficiency, all classes of fabric of whatever type of yarn they were made. The new fibre did not replace cotton, but lent itself to the decoration of cotton fabrics. He believed that the increased use of the synthetic fibres, the development of which was mainly due to British skill and enterprise, would be a factor in restoring, in part at any rate, our great textile industries to prosperity, which would in time beneficially affect their own particular industry. The Association manufactured pure cotton cellulose—one of the basic materials of artificial silk—of a quality equal, if not superior, to anything produced. The finishing of cotton goods—one of the main activities of the Association—was also receiving close attention. A final dividend was declared of 1s. 2d. per share, making 1s. 6d. per share for the year.

CELANESE CORPORATION OF AMERICA

It is announced that Messrs. Morgan & Co., the American financiers, have undertaken an issue of £5,000,000 preference shares on behalf of this company. The proceeds of the issue, together with £1,200,000 to be raised by the offer to existing holders of the common shares, are to be utilised in increasing the company's plant, and it is estimated that production will thereby be trebled and quadrupled.

SCOTTISH ARTIFICIAL SILKS LIMITED

This company has been formed with a capital of £250,000, divided into 760,000 preferred ordinary shares of 5s. each, and 1,200,000 deferred shares of 1s. each, and will manufacture artificial silk by the viscose process. The Tongland Works, near Kirkcudbright, Scotland, have been acquired, with very valuable water rights. The company has also taken over the Providence Mill, Hyde, Cheshire, well known for its manufacture of special yarns for the Nottingham, Leicester and foreign trade, and the directors propose to continue this trade, and in addition to make the yarn suitable for artificial silk fabrics. The company has secured the services of Mr. H. Kindermann as consulting engineer and technical adviser, and also proposes to engage Dr. Otto Ruff, Professor and Director of the Technical College, Breslau, as consulting chemist. The following are the directors: J. Morison, chairman; J. T. Rostern (late with Messrs. Courtaulds, Ltd.), managing director; A. Morris, Lieut.-Colonel A. F. Inglis, O.B.E., N. H. Macalister, J.P., C. P. Williams, M.Sc., J.P., M.P., and R. C. Hannay. The registered address of the company will be 145, St. Vincent Street, Glasgow.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£8 15s. per ton. f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 *Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.
 Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.

Black.—£35 per ton, barrels free.
 Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron".—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals, 8d.—9d. per lb. Crude 60's, 2s. 4d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 3d. per gal. Pale, 95%, 2s.—2s. 2d. per gal. Dark, 1s. 9d.—2s. 1d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 8d.—2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol.—1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—8½d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/160, 1s. 3d.—1s. 11d. per gal. Solvent 95/160, 1s. 5d.—1s. 6d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals, £11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—72s. 6d.—82s. 6d. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.).—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.
 Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzdine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorobenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylylene Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—Cryst. £40—£41 per ton. Powder £44—£45 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 6½d.—1s. 7½d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. pulv. 1s. 3½d.—1s. 10d. per lb. Crystals 1s. 10d.—1s. 11d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24—£27 per ton, Powder £26—£29 per ton, according to quantity, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 4d.—2s. 5d. per lb. Potassium.—1s. 11d.—2s. per lb. Sodium.—2s. 2d.—2s. 3d. per lb. All spot.

Calcium Lactate.—1s. 3½d.—1s. 5d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Creosote Carbonate.—6s. per lb.

Ethers: Prices for Winchester quarts; dozen Winchester quarts; carboys or drums; and 10 cwt. lots respectively; 730—1s. 2½d.; 1s. 2d.; 1s. 1½d.; 1s. 0½d.; 720 tech.—1s. 5½d.; 1s. 5d.; 1s. 4½d.; 1s. 3½d.; 720 pur. (Aether P.B. 1914)—2s. 4d.; 2s. 3½d.; 2s. 3d.; 2s. 2d.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiaicol Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ½ lb., 9s. 6d. per doz.; ¼ lb., 6s. 6d. per doz.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—4d. per lb., 22s. per cwt., according to quantity.

Magnesium Carbonate.—Light Commercial £31 per ton net.

Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 3d. per lb. net. Synthetic detached crystals, 11s.—14s. 6d. per lb., according to quantity; Liquid (95%), 12s. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig. 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonal.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—3s. per lb.

Phenazone.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar 100s. per cwt., less 2½% for ton lots).

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 2d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Resorcin.—4s. per lb. spot.

Saccharin.—55s. per lb., and lower in quantity.

Salol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonal.—7s. 6d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s. 1d.—2s. 2d. per lb.

Thymol, Puriss.—10s. 6d.—11s. 6d. per lb., according to quantity. Natural.—12s. 6d. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (ex Anethole).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 9d. per lb.

Ethyl Cinnamate.—7s. 6d. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. Geraniol (Palmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(ex Bois de Rose) 15s. per lb.—(ex Shui Oil) 10s. 6d. per lb. Linalyl Acetate.—(ex Bois de Rose) 18s. per lb.—(ex Shui Oil) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—32s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—17s.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—28s. 6d. per lb. Bourbon Geranium.—14s. 6d. per lb. Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 3d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 1s. 11d. per lb., Ceylon, Pure, 1s. 9d. per lb. Clove, pure—6s. per lb.

Eucalyptus, 75/80%.—2s. 3d. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz. Palma Rosa.—10s. 6d. per lb. Peppermint.—Wayne County, 18s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 6d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug. 18th.

The remainder are those accepted.

I.—Applications

Boyd. Furnace walls. 15,556. June 10.
British Dyestuffs Corp., Hailwood, and Shepherdson. Manufacture of finely-divided substances. 15,171. June 7.
Comp. Gén. de Construction de Fours. Tunnel kilns. 15,006. June 7. (Fr. 5,626.)
Geigy A.-G. Preparation convertible into dispersions. 15,311. June 8. (Ger., 18,626.)

Filters etc. 15,003. June 7. (U.S., 7.6.26.)
 Farbenind. Recovery of reaction products from
 res. 15,170. June 7. Production of cleansing etc.
 agents. 15,615. June 11.
 Machin and Ringrose. Furnaces. 15,059. June 7.
 Paterson. Filtering-apparatus. 15,214. June 7.
 Sacchi. Apparatus for effecting reactions between fluids.
 15,178. June 7.
 Soc. Ind. de Briqueterie et Céramique. Drying apparatus.
 14,033. June 7. (Fr., 30.7.26.)
 Steam Production Corp. Furnaces. 15,622. June 11.
 (U.S., 31.7.26.)
 White. Separation of liquids of different specific gravities.
 15,213. June 7.
 Wood. Grinding, mixing, etc. machinery. 15,063.
 June 7.
 Wright. Apparatus for effecting intimate contact of
 gases and liquids. 15,353. June 9.

I.—Complete Specifications

17,128 (1926). Lityen. Tumbling-mills. (266,664.)
 32,346 (1926). Kreutzberg. Pulverisers. (272,111.)
 3099 (1927). Marx. See XXIII.
 6810 (1927). Ludwig. Improving the utilisation of heat
 in drying drums. (267,543.)
 13,192 (1927). Fowler & Co. (Leeds), Ltd., and Fowler.
 Mixing-machines. (272,151.)
 *8303 (1927). I.-G. Farbenind. Drying-agent for gases.
 (272,173.)
 *14,527 (1927). Scheidt. Bag filter. (272,209.)
 *14,560 (1927). Cerini. See VII.
 *15,006 (1927). Comp. Gén. de Construction de Four.
 Tunnel kilns. (272,238.)

II.—Applications

Akt. Separator-Nobel, and Malm. Removal of paraffins
 from fluid hydrocarbons. 15,183. June 7.
 Betts and Pearson. Pulverised fuel for steam-raising
 furnaces etc. 15,573. June 11.
 Comp. des Mines de Bruay. Distillation of mineral fuels.
 15,376 and 15,379. June 9. (Fr., 14.6.26 and 18.12.26.)
 Delplan and Quairiaux. Washing coal etc. 14,983. June
 7. (Belg., 4.6.26.)
 Hodeige. Washing coal etc. 15,398. June 9.
 I.-G. Farbenind. Bleaching mineral oils etc. 15,205.
 June 7. (Ger., 21.7.26.) 15,262. See III. Destructive hydro-
 genation of carbonaceous materials. 15,525. June 10. (Ger.
 11.6.26.) Treatment of coal tars etc. 15,526. June 10.
 (Ger., 11.6.26.)
 Johnson (I.-G. Farbenind.). Treatment of montan wax.
 15,414. June 9.
 Linnmann. 15,255 and 15,359. See III.
 Paucy. Calorimeter. 15,086. June 7.
 Trautmann. Extraction of hydrocarbon oils from coal.
 15,386. June 9. (Ger., 11.6.26.) Extracting benzene.
 15,642. June 11. (Ger., 16.6.26.)

II.—Complete Specifications

3454 (1926). I.-G. Farbenind. Method of working with
 carbon monoxide under pressure. (247,217.)
 12,705 (1926). Humphreys & Glasgow, Ltd., and Stelfox.
 Manufacture of water-gas. (272,026.)
 20,884 (1926). Soc. pour l'Exploit des Proc. Urbain.
 See VII.
 27,029 (1926). Levinsohn. Gas-analysis apparatus.
 (272,092.)
 *13,601 and 13,820 (1927). I.-G. Farbenind. Manufacture
 of products from coal, tars, mineral oils, and the like. (272,190
 and 272,194.)
 *14,983 (1927). Delplan and Quairiaux. Washing coal
 schlamms etc. (272,235.)

III.—Applications

Fairweather (Selden Co.). Purification of aromatic hydro-
 carbons. 15,169. June 7.
 I.-G. Farbenind. Manufacture of hydrocarbons. 15,262.
 June 8. 15,526. See II.
 Johnson (I.-G. Farbenind.). Manufacture of hydrocarbons.
 15,411 3. June 9.
 Linnmann. Benzol separators. 15,255 and 15,359. June
 8 and 9. (Ger., 8.6.26.)
 Wessel. Distillation of coal tar. 15,252. June 8. (Ger.,
 29.6.26.)

III.—Complete Specification

*13,601 (1927). I.-G. Farbenind. See II.

IV.—Applications

British Dyestuffs Corp., and Silvester. Manufacture of
 dyes. 15,005. June 7.
 Carpmæl (I.-G. Farbenind.). Manufacture of sulphonic
 acids. 14,990. June 7. Manufacture of benzanthrone
 condensation products. 15,425. June 9. Manufacture of
 condensation products of anthraquinone. 15,562. June 10.
 Manufacture of vat dyestuffs of anthraquinone series.
 15,631. June 11.
 I.-G. Farbenind. Manufacture of perylene compounds.
 15,422. June 9. (Ger., 9.6.26.)
 Johnson (I.-G. Farbenind.). Anthraquinone dyestuffs.
 15,163. June 7. Manufacture of dyestuffs. 15,416 and
 15,528. June 9 and 10.

IV.—Complete Specifications

30,990 (1925). Badische Anilin & Soda Fabrik. Manu-
 facture of anthraquinone derivatives. (244,463.)
 5891 (1926). Marks (Du Pont de Nemours & Co.). Pro-
 duction of N-dihydro-1 : 2 : 1' : 2'-anthraquinone azine.
 (271,942.)
 7577 (1926). I.-G. Farbenind. See VI.
 8312 (1926). Soc. Chem. Ind. in Basle. Manufacture of
 azo-dyestuffs containing metal. (249,884.)
 12,260 (1926). Dyestuffs Corp., and Mendoza. Pyrazolone
 dyestuffs. (272,024.)
 13,023 (1926). I.-G. Farbenind. Manufacture of dyestuffs.
 (252,300.)
 16,012 (1926). Soc. Chem. Ind. in Basle. Manufacture of
 azo-dyestuffs and chromium derivatives thereof. (254,708.)
 28,907 (1926). I.-G. Farbenind. Manufacture of amines
 of the cyclohexano series. (261,747.)
 *14,851 (1927). I.-G. Farbenind. Manufacture of
 α -anthraquinonyl ketones. (272,225.)

V.—Applications

Calvert. Treating fibres etc. 15,228 and 15,230. June 8.
 Manufacturing artificial silk etc. 15,229. June 8.
 Carpmæl (I.-G. Farbenind.). Protecting wool from insects
 etc. 15,569. June 10.
 Micklethwaite. Treating wool fibres etc. 15,929. June 7.
 Plastic, Inc. Making paper etc. 15,287. June 8. (U.S.,
 25.3.27.)

V.—Complete Specifications

2441—2 (1926). I.-G. Farbenind. Production of celluloid-
 like masses. (247,174 and 263,076.)
 6114 (1926). Standard Telephones and Cables, Ltd.
 (Western Electric Co., Inc.) See XI.
 29,489 (1926). Heberlein & Co. See VI.
 2413 (1927). Syntheta A.-G. Manufacture of artificial
 silk. (265,577.)
 11,989 (1927). Bonnard. Treating crêpe waste. (270,727.)
 *30,160 (1926). Heberlein & Co. See VI.

VI.—Applications

British Dyestuffs Corp., Baddiley, Brightman, and Chorley.
 Dyeing. 15,180. June 7.

Chem. Fabr. vorm. Sandoz. Treating cellulose fibres with alkali. 15,544. June 10. (Ger., 29.10.26.)

Marks (Du Pont de Nemours & Co.). Printing with vat dyes. 15,280. June 8.

Mond (I.-G. Farbenind.). Bleaching linen, hemp, etc. 14,989. June 7.

VI.—Complete Specifications

7577 (1926). I.-G. Farbenind. Production of azo-dyestuffs on silk. (253,865.)

18,215 (1926). I.-G. Farbenind. Production by dyeing of fast mixed shades on silk. (263,088.)

29,489 (1926). Heberlein & Co. Chemically varying artificial fibres. (261,794.)

*30,160 (1926). Heberlein & Co. Chemically varying vegetable fibres or artificial fibres. (272,165.)

VII.—Applications

Dicker (Chemical Products Co.). Production of ammonium phosphate. 15,566. June 10.

I.-G. Farbenind. Manufacture of active silica. 15,415. June 9. Method of storing dibasic calcium hypochlorite. 15,515. June 10. (Ger., 18.8.26.) Manufacture of active silica gels. 15,527. June 10.

Kolbert. Manufacture of a solid alcoholic solution of iodine. 15,265. June 8.

Mond (Metallbank und Metallurgische Ges.). Disintegrating liquid alumina. 15,011. June 7.

Petersen. Manufacture of sulphuric acid. 15,115. June 7.

Sacchi. Production of hydrogen-nitrogen mixtures. 15,179. June 7.

VII.—Complete Specifications

299 (1926). I.-G. Farbenind. Production of phosphoric acid. (246,128.)

3470 (1926). I.-G. Farbenind. Production of phosphorus. (247,219.)

5767 (1926). Carpmael (I.-G. Farbenind.). Manufacture of new complex antimony compounds. (271,940.)

13,086 (1926). Akt. Norsk Aluminium Co. Manufacture of aluminium oxide. (252,399.)

16,365 (1926). Smith. Conversion of lead sulphide into lead carbonate. (272,053.)

20,884 (1926). Soc. pour l'Exploit. des Proc. Urbain. Manufacture of phosphorous or phosphoric acid and activated charcoal. (257,917.)

25,659 (1926). California Cyanide Co., Inc. Making cyanides of alkali-forming metals. (261,722.)

28,321 (1926). Müller. Purifying gases for the synthesis of ammonia. (261,388.)

30,646 (1926). I.-G. Farbenind. Purification of hydrogen obtained by the interaction of phosphorus and steam. (262,455.)

*14,560 (1927). Cerini. Apparatus for osmotic purification of solutions of caustic soda etc. (272,211.)

VIII.—Application

Quartz et Silice. Manufacture of glazed silica articles. 14,966. June 7. (Fr., 15.7.26.)

VIII.—Complete Specifications

580 (1926). I.-G. Farbenind. Production of potash glass. (245,785.)

4837 (1927). Quartz et Silice. Manufacture of silica glass articles. (266,711.)

IX.—Application

Doughty. Producing coloured cement etc. 14,901. June 7.

IX.—Complete Specifications

10,848 (1926). Schumacher'sche Fabr. Ges. Manufacture of porous artificial stone. (251,964.)

10,849 (1926). Schumacher'sche Fabr. Ges. Manufacture of artificial filter stones. (251,965.)

*29,295 (1926). Forssen. Manufacture of hydraulic cements. (272,163.)

X.—Applications

Aluminium-Ind. A.-G. Electrolytic extraction of aluminium from aluminium alloys etc. 15,154. June 7. (Ger., 7.6.26.)

Berger. Manufacture of zinc etc. 15,304. June 8. (Fr., 11.6.26.)

Carpmael (I.-G. Farbenind.). Precipitation of copper. 15,426. June 9.

Coley. Manufacture of zinc. 15,041 and 15,444. June 9.

Treatment of ores etc. 15,443. June 9.

Cornish Tin Smelting Co., Ltd., and Davey. Refining tin. 15,297. June 8.

Ellis (Anaconda Copper Mining Co.). Production of copper cakes. 15,172. June 7.

Moulin (Pierron). Manufacture of zinc etc. 15,304. June 8. (Fr., 11.6.26.)

Potts (Electro Metallurgical Co.). Wrought articles of chromium alloy. 15,333. June 9.

Rogers. Coating iron or steel plates with brass. 15,051. June 7.

Smith. Treatment of ores etc. 15,150. June 7.

Verein. Stahlwerke. Treating drawn steel wire. 15,009. June 7. (Ger., 4.6.26.)

X.—Complete Specifications

19,285 (1926). Sempell. Bearing-metal. (272,065.)

32,876 (1926). Krupp Grusonwerk. Treatment of zinciferous flue dust. (265,558.)

33,070 (1926). A.-G. Brown, Boveri, & Cie. Electric smelting-furnaces. (263,872.)

*15,009 (1927). Verein. Stahlwerke. Improving the tensile qualities of drawn steel wire. (272,240.)

*15,154 (1927). Aluminium-Ind. A.-G. Electrolytic extraction of pure aluminium from crude aluminium alloys, etc. (272,246.)

XI.—Applications

Aluminium-Ind. A.-G. 15,154. See X.

British Thomson-Houston Co., Ltd. Treating filaments. 15,121. June 7. (U.S., 9.6.26.)

XI.—Complete Specifications

6114 (1926). Standard Telephones and Cables, Ltd. (Western Electric Co., Inc.). Treatment of fibrous material for electric insulating. (271,948.)

7884 (1926). Scanes and Metropolitan-Vickers Electrical Co., Ltd. Electrical insulating compounds. (271,979.)

11,514 (1926). Harrison and Campbell. Electric batteries. (272,013.)

19,186 (1926). Norske Akt. for Elektrokem. Ind. Electrodes for electric furnaces. (262,722.)

33,070 (1926). A.-G. Brown, Boveri, & Cie. See X.

*13,781 (1927). British Thomson-Houston Co. Electric furnaces. (272,192.)

*14,861 (1927). Brown, Boveri, & Cie. Electric furnaces. (272,227.)

*15,154 (1927). Aluminium-Ind. A.-G. See X.

XII.—Application

Harvel Corp. Treating cashew-nut shell oil etc. 15,203—4. June 7. (U.S., 8.6.26.)

XIII.—Applications

Edser and Fowler. Paints. 15,318. June 8.

Holzverkohlungs-Ind. A.-G., and Seib. Manufacture of white lead. 15,432. June 9.

XIII.—Complete Specifications

16,365 (1926). Smith. See VII.

6381 (1927). Turner. Paints or protective compositions. (272,142.)

*13,038 (1927). Rubber Latex Research Corp. Rubber compositions. (272,187.)

XV.—Application

Manfred. Preparations of albumen-containing plastic masses. 14,889. June 7. (Czecho-Slovakia, 26.11.26.)

XV.—Complete Specifications

10,083 (1926). L.-G. Farbenind. Manufacture of tanning-agents. (260,543.)

*13,945 (1927). Botson. Treatment of hides and skins preliminary to tanning. (272,195.)

*14,198 (1927). Guillemin. Impermeabilising and protecting leather. (272,197.)

XIX.—Applications

Clark (Dry Milk Co.). Irradiating milk solids with ultra-violet rays. 15,639. June 11.

Fisher and Jones. Manufacture of flour. 15,542. June 10.

Günther. Conserving animal foodstuffs. 15,000. June 7.

Oram and Oram. Compound for making bread etc. 15,138. June 7.

XX.—Applications

Blugden, and Howards & Sons. Manufacture of crystalline menthol. 15,294. June 8.

Etabl. Poulenc Frères, and Fourneau. Manufacture of formyl derivatives of 2-oxy-4-amino-phenyl-arsinic acid etc. 15,197. June 7. (Fr., 29,10,26.)

Hoffmann-La Roche & Co. Product for internal disinfection. 14,935. June 7. (Ger., 4,6,26.)

Kolbert. 15,265. See VII.

XX.—Complete Specifications

5767 (1926). Carpmal (L.-G. Farbenind.). See VII.

6977 (1926). Synthetic Ammonia & Nitrates, Ltd., Smith, and Smith. Production of acid amides and salts. (271,969.)

11,816 (1926). L.-G. Farbenind. Manufacture of compounds containing carbocyclic or heterocyclic rings. (251,997.)

26,777 (1926). Chem. Fabr. vorm. Schering. Obtaining the active constituents of germ glands. (261,356.)

32,725 (1926). Grouhkin. Preparation of diiodotrimethylamine. (272,113.)

979 (1927). Chem. Fabr. vorm. Schering. Manufacture of chloriodo compounds of alphaaminopyridine and its derivatives. (264,508.)

7460 (1927). Rupe. Manufacture of unsaturated aldehydes. (267,954.)

*22,052 (1926). Soc. Chim. de la Grande-Paroisse. Manufacture of formaldehyde. (272,155.)

*14,337 (1927). Stiepel. Manufacture of hydroxy acids. (272,198.)

*14,935 (1927). Hoffmann-La Roche & Co. Product for internal disinfection. (272,232.)

XXI.—Complete Specification

26,797 (1926). Bausch, Bausch, Bausch, and Bausch. Making unsensitised films for photographic and cinematographic purposes. (260,306.)

XXIII.—Applications

Boehringer, and Boehringer Sohn. Production of disinfecting agents. 15,572. June 10. (Ger., 8,3,26.)

Keleti. Production of disinfectants etc. 15,550. June 10. (Hungary, 12,6,26.)

XXIII.—Complete Specification

3099 (1927). Marx. Clarification of liquids and recovery of the solid matter. (272,130.)

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Cod liver oil (607); cod oil (608); crockery, glassware (Commercial Bureau, Australia House, Strand, W.C.2. Ref. No. 457). *Austria*:

Paper, stationery, Indian ink (617). *British India*: Belting, lubricating oils, ferro-manganese, steel tyres and axles (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1); steel and cast-iron pipes (A. 4791). *Canada*: Zinc sheets (611). *Chile*: Leather (629). *Germany*: Leather, ox-leathers, grained and split chrome leathers (622). *Hungary*: Leather (623). *Italy*: Chemicals (624). *Japan*: Metals (626). *South Africa*: Tyres (616); aluminium paint (B.X. 3568).

British Industries Fair

According to an official announcement made on June 17, the holding of the British Industries Fair is definitely assured for the next three years, the British Government having leased the White City, Shepherd's Bush, for the London section of the Fair for the necessary periods in 1928, 1929, and 1930.

The next Fair, which will be held simultaneously in London and Birmingham from February 20 to March 2, will be by far the largest British Industries Fair on record. The available exhibiting area in London exceeds the space provided there last year by 100,000 sq. ft. Extensions amounting to 80,000 sq. ft. are to be made at Castle Bromwich, Birmingham, and additional space up to 100,000 sq. ft. is in readiness.

Application forms for space in London are being sent out this week by the Department of Overseas Trade to approximately 10,000 British manufacturers. The space already applied for in the Birmingham section amounts to double the figure for the corresponding day last year.

Safeguarding of Key Industries

The Board of Trade give notice that representations have been made to them under Section 10 (5) of the Finance Act, 1926, regarding the following articles:—Ethylene bromide, lead tetra-ethyl, monochlor-naphthalene, and R potassium hydroxide.

Communications regarding the applications should be addressed to the Principal Assistant Secretary, Industries and Manufactures Department, Board of Trade, Great George Street, S.W.1, within two months from the date of this notice (June 15, 1927).

News from Advertisements

1. The Department of Scientific and Industrial Research announce various vacancies for research chemists (p. x).

2. A qualified chemist is wanted immediately for a mine on the Eastern Mediterranean coast (p. x).

3. The Egyptian University, Cairo, require a glass blower (p. x).

4. An expert in micro-chemical methods and photomicrography seeks appointment (p. x).

5. A technical and analytical chemist seeks partnership (p. x).

No. 26

EDITORIAL

The Chemist and Druggist

THESE two nouns not only are the title of a well-known journal, the last number of which we have read with great interest and pleasure, but they form the description of many thousand people who are interested in the preparation and the sale of drugs. The circumstances are such that we must be particularly careful how we allude to a matter with such potentialities of discord as the relationship between the chemist and the chemist and druggist. That a sharp and rigid line, perhaps even more than a line, can and should be drawn between these two occupations is obvious. When we have attended meetings of the Society of Chemical Industry in provincial cities we have more than once been courteously greeted by an entire stranger, who has made some complimentary remark about the Society, and then asked our candid opinion about Yadil or some equally valuable fluid. We have usually explained that we had no chemical pretensions ourselves, and that our chemical friends who allowed us to attend their meeting belonged to an entirely different and much superior branch of mankind, and hardly were aware of the existence of the other and much lower beings who had no moral right to use the term chemist. We ourselves make a point of invariably using the term "pharmacy" instead of "chemist's shop" except when we ask a maid, or a child, or the gardener to buy something for us in that establishment. But as we never have occasion to mention the establishment unless we are conversing with persons of inferior mental equipment, we fear that it is only on very rare occasions that our invariable practice comes into operation. Moreover, we find there is a danger that some of the potent grave and reverend signiors of our profession do not hold themselves duly aloof. We concealed, so far as possible, from our neighbours the fact that our last president was a pharmaceutical chemist; we cannot

conceal the fact that our reigning president spends his time in pharmacy and drugs, because his own presidential address is, we are informed, abundant evidence of his interest in these matters; a predecessor in the presidential chair, Sir William Pope, also has studied drugs, and, in conjunction with pharmacologists, has prepared drugs which in his and their opinion are even more meritorious than Yadil itself. Pharmacologists differ from pharmacists, just as presbyters differ from priests. The past Honorary Treasurer of the Society, Mr. D. Lloyd Howard, is this year's chairman of the British Pharmaceutical Conference, and from his portrait, which adorns the last number of the *Chemist and Druggist*, he does not seem to have altered his appearance much since he carried the Society's purse and pass-book. We could give other instances of this sort, but we refrain: it is obvious that our nomenclature requires revision. The chemotherapeutical practitioners, the pharmacologists and the biochemists are not to be confounded with mere pharmaceutical people; their methods are different, and the subjects they study are different: and yet we find in the pharmaceutical conference reference to a paper on the adjustment of p_H for the stability of ammonium acetate, to another paper on the presence of vitamins A and B in orange juice, and to another paper by the Burroughs scholar in the Pharmaceutical Society's Research Laboratory. The last number of the *Chemist and Druggist* contains an article on the Beginnings of Pharmacy, with pictures from an early MS. of Dioscorides, photographs of Egyptian and Assyrian vases and inscriptions, Greek and Roman relics, extracts from a XV Century MS. of Galen, and pictures of many men of science, some of whom were both chemists and chemists and druggists. This historical sketch of the evolution of the art of compounding medicines is well written, well printed, and beautifully illustrated, and contains many pictures and

statements which we should have been glad to have seen in CHEMISTRY AND INDUSTRY. We think that if the last four presidents of the Society of Chemical Industry, the president of the Chemical Society, and the Chief Government Chemist would only meet and draw up logical definitions of the various classes mentioned in this short editorial note, we should all get accustomed to the accurate use of the various terms, and, having become fluent in these, we could then commence a vigorous campaign for the education, first of the public, and then of the House of Commons, the House of Lords we regard as hopeless in this respect. There is a grave danger that chaos may prevail in that great department of learning which adjoins chemistry, pharmacy, physiology, biology and medicine. This chaos may be avoided by exact definitions, a few weeks ago we thought of a good definition of the word "chemist" ourselves; unfortunately it escaped us, and we have not been able to recall it; it is not forgotten; it is in the sub-conscious part of our mind, and we shall probably think of it immediately after going to press. It should be as easy to define chemist, as lawyer or engineer, and as profitable. While the chaos we have mentioned continues to exist, it is comforting to think that the bio-chemists in this country will continue the excellent work they are now engaged in, and that the pharmaceutical chemists, of the type of Mr. Carr and Mr. Lloyd Howard, will continue their excellent work, and that the chemo-therapeutical chemists will invent drugs which will rival salvarsan and quinine. The trouble is that chemistry has already invaded most of the professions, industries and arts, and will invade the residue very speedily, and unless we prune our words in due course the luxuriant growth will bewilder the journalists and the newspaper-reading public, and the words will be so distorted from their true meaning that all nicety of expression will be lost, even though everybody will understand perfectly well what is meant. We are all in favour of nicety of expression, and shall be grateful for a little guidance. It is a pity that the general public is not more interested in exact and scientific methods; we visited our old haunt, the Law Courts, the other day, and listened to certain learned gentlemen discussing the condensation of fatty acids and phenols with a view to a decision by a judge already profoundly learned in equity and absorbing chemistry with great rapidity. The case, they told us, was of extraordinary interest, would last a fortnight or three weeks, and cost an appalling lot of money, and yet the court was nearly empty: the general public, unfamiliar with the technical terms, tired of the first witness after he had been in the witness-box only a day; his subsequent evidence, though equally interesting, attracted no gallery, and we have, so far, seen no report of the proceedings in the morning papers. We did not intend our editorial to wander in this way; our intention was to describe Mr. Chaston Chapman's address on the Profession of Chemistry, and to bring in somehow a reference to the Alembic Club, which is domiciled in Edinburgh, and was omitted from our recent account of that city. We cannot think how we have gone astray. "*Amphora coepti institui, currente rota curvaceus exit!*" It was a wine jar that was to be moulded: as the wheel runs round why does it come out a pitcher?

THE COMMERCIAL SYNTHETIC RESINS AND THEIR PRODUCTS*

By HERBERT W. ROWELL

(Concluded)

Presses.—A semi-automatic press is used for rapid output from a multiple mould for small articles or the more convenient handling of a large single impression mould.

The piston portion of the mould is attached to the double-action ram, which alternately presses upon and withdraws the piston, while the other half of the mould is attached to the bed frame. Ejector pins, attached to a small ram below the mould, work in the lower half of the mould and push out the articles. The mould contains its own heating arrangements.

Telephone earcaps are moulded with the screw thread and hole complete. If it were not for the projecting rim at the cord end of the post office telephone earpiece the trumpet-shaped portion could be moulded in and ejected from an ordinary type piston mould. A special angle press used for such articles carries the core and piston portion of the mould on the overhead ram, one half of the cavity portion of the mould attached to the horizontal ram and the other half to the press frame. The horizontal ram closes the two halves of the cavity portion, the powder is added and the piston brought down, and when both rams are withdrawn the article with its projecting rim falls out of the split cavity portion.

Finishing.—Thin fins or flashes found on many mouldings as they come from the mould are removed by filing, grinding or turning with the help of ingenious jigs and tools to reduce labour costs. Holes which are inconvenient to mould have to be drilled and sometimes tapped or slots sawn or milled out. A highly polished mould gives a corresponding finish to the goods, but machined spots and goods from dull moulds can be brought to a good finish by mopping and buffing. The depressed moulding, as in radio dial scales, trade or other markings, can be filled with coloured composition.

LAMINATED RESIN-PAPER PRODUCTS

In the form of sheets, blocks, tubes, rods and trough-moulded shapes, the makers of modern electrical plant require this material for insulation purposes. It has many other uses in other industries, as it is stronger than the powder mouldings, and large sheets and tubes can be obtained.

There are two distinct qualities. The lower grade, which is called "laminated" or "rolled," consists of sheets of paper cemented together with, and containing 25% to 35% of, resin. The higher grade contains 45% to 55% of resin, and is usually called "moulded sheet" or "rolled and moulded tube," and is made by a more expensive process involving complete impregnation of the paper and baking under heavy pressure. The lower grade is a good insulator, is practically non-inflammable, can be sawn, punched and machined, but will absorb several per cent. of its weight of water when immersed

* Read before the Birmingham Section on March 8, and illustrated by an exhibition of numerous products, moulds, and materials.

and is liable to split along the laminations. It is quite satisfactory for many electrical purposes, and has the larger sale. In the higher grades, as the paper is impregnated with resin the mass loses nearly all its laminated structure. It absorbs practically no water, it can be drilled, tapped and screwed without splitting, its tensile and shearing strength is 5 to 7 tons per sq. in., it can be engraved like metal, and the surface and cut edges can be highly polished. It will withstand a temperature of 150° C. continuously, and is resistant to solvent and

required a solution of the "treacle" in methylated spirit may be used, which, however, adds to the cost.

To make sheets or boards, the paper is cut into suitable pieces, made into a pack with coated side against plain side, placed between polished metal sheets and compressed between the hot plates of a large press. The resin first melts and partly impregnates the paper, then hardens and forms the cement which binds the mass together.

To form tubes, the coated paper is fed from the rolls

FIG. 5

Angle or two-direction press, showing moulds fixed for making telephone handles

chemical attack as in the case of powder mouldings. In the manufacture of the lower grade of laminated goods, a suitable grade of paper is coated on one side with resin in its "treacle" stage in a machine such as is used for spreading rubber solution on to cloth. In its passage over the hot plates the paper is dried and the treacle polymerises to a resin state in which it is not sticky when cold. This enables the coated paper to be again made into convenient rolls without sticking. Owing to the high viscosity of the "treacle" there is no serious penetration of the paper, but if better impregnation is

to a machine which wraps it tightly around a steel mandrel and at the same time heats the resin rapidly to above its melting point. Square and round tubes from $\frac{1}{8}$ -in. to 3 in. bore and up to 6 ft. long, or cylinders from 3 in. to 3 or 4 ft. diam. by 6 ft. or longer, are manufactured with wall thickness up to an inch or more.

The tube while still on its mandrel is baked at a temperature below 100° C. for a day or more and finally at a higher temperature according to the practice of the maker. He has to dry the paper thoroughly and bake his resin to its final stage without blistering or reducing

... of the tube. The mandrel is then withdrawn and any wax paper or other preparation used to prevent sticking to the mandrel is removed from the bore.

Moulded paper-resin products.—A better grade of paper is used for this type, and after drying it is passed through a machine which impregnates and leaves an even coat of resin solution in alcohol on both sides of the paper. The impregnated paper passes continuously through a heated oven in the larger factories and is re-rolled when cold. Sheets of thickness from $\frac{1}{8}$ -in. to $\frac{1}{2}$ -in. and blocks up to 3 in. or 4 in. thick are made in a similar way to the laminated sheet by baking in large hydraulic presses.*

The rolling of tubes is much more difficult than in the case of the lower quality, as the paper is sticky when hot on both sides. After rolling on to the round, square or hexagonal mandrel, the tube and its mandrel are placed in a mould and heavily compressed and baked in the hydraulic press.

In this manner tubes and rods having mechanical strength, moisture-proof, machining and electrical properties equal to the best grade sheet can be made up to 4 in. diam. or more and 4 ft. long, as well as angles, troughs and other shapes. The tubes can be screw-jointed or cemented to form longer lengths, and are supplied accurate in internal and external diameter to within 0.002 in. Only one firm in this country manufactures this kind of tube under the name of "Tufnol," and two firms in the United States manufacture a similar moulded type using Bakelite resins. Asbestos is used in place of paper to obtain satisfactory resistance to 350° C. in the "Asbestos-Tufnol" sheets and tubes.

Fibrous mouldings.—To obtain greater tensile strength and shock resistance than is obtainable in wood meal powder mouldings, a proportion of asbestos or vegetable fibre is sometimes added as filler. This gives a more bulky powder, the fins are not so clean, and the surface finish is often rather poor. Flanged bushings, trays, cup washers and other shapes with a high finish are moulded from paper pulp and phenol-aldehyde resins. They are practically unbreakable, and can be drilled or machined in any direction without splitting.

Another important application is the manufacture of small and large spur wheels and pinions which wear better than raw hide, and are noiseless. The smaller wheels of this type are now largely used in timing gear and magneto drives in motor-cars. Cotton duck cloths are impregnated and moulded into laminated blocks, which are then machined to form the toothed wheels or worm drives of usual type. Very small wheels can be punched from paper-resin sheet or may be moulded from fibrous powders.

Cements.—The "treacle" stage resin or a solution of the "resin" stage forms a transparent cement with practical applications. Fillers and colours may also be included. Mouldings, paper-resin sheet and tube, broken china, rough metal and unglazed porcelain can be joined, and after baking carefully to avoid bubbles, give heat-resistant and perfectly waterproof

and oilproof joints. Flanged steam pipe joints can be packed with asbestos washers soaked in the resin which bake to hard joints automatically. Paint brushes have their bristles cemented in place with Bakelite resin, and no solvent will remove them.

After proper baking, these resins do not stick to any highly-polished surface, and, generally speaking, such cements or any other phenol-aldehyde product is of no practical value until baked to its final stage. Abrasives such as carborundum and emery are mixed with this cement and moulded into grinding wheels. In place of the usual emery cloth disc glued to a face plate, the emery grains can be cemented directly to the plate to form a disc grinder. Heating to nearly red heat will detach the coating, which can be renewed, and gives more satisfactory service than cloth discs. Another interesting application is the formation of steam pipe insulation sections from long fibre asbestos cemented together with a solution of the resin and baked to a robust, permanent shape.

Chemical-proof linings for vats and large pipes have been made by mixing silica or other inert powder or grains with phenol-aldehyde resins. Tiles or other shapes of earthenware cemented into place with similar mixtures are regularly used in pumps and tanks.

MODIFIED RESINS

Methods of producing flexible or elastic final products of phenol-aldehyde resin have been suggested which are based on the addition of substances which either dissolve or are dissolved in the hard-baked final resin. The use of an excess of phenol or *o*-cresol has already been noted, and a number of substances like naphthalene, ricinoleic acid, chloro-naphthalenes, and di-phenylamin[•] have been mentioned in patent and other literature. No really flexible product has been produced commercially, because whilst these added substances produce flexibility they reduce melting or softening point, reduce tensile strength, or otherwise damage the good properties of the resin.*

Oil-soluble resins of the phenol-aldehyde type have been sought for varnish work; in fact, this was the main object of the original investigators, but the only commercial types are those known as "Albertols" patented by Albert and Berend (E.P., 1914, 15,875). These are apparently a phenol-aldehyde resin containing excess phenol or cresol heated with 30—50% of common rosin for some time. The resins may need to be "run" still further by the varnish maker to render them entirely soluble in linseed oils and the usual solvents.

Aylesworth, Robinson and others have patented the use of *o*- and *p*-cresols with formaldehyde and other agents to produce oil-soluble resins without rosin addition, but these do not appear to be on the market.

Furfural has been produced at a low price from oat hulls, and has been condensed with phenols of various kinds to produce resins. The resins are black or practically so, and have therefore only been used in limited quantity for commercial purposes.

* Some highly polished natural wood grain boards of Bakelite-paper were exhibited in which the top layer of paper is printed with a photographic reproduction of the timber grain in natural colour. Such panels do not warp, and are practically indestructible.

* Among the large assortment of synthetic-resin products exhibited were some samples of quite flexible cloth and paper which are intended to replace oiled silk and varnished cloth, and which may develop commercially for electrical insulation.

A French resin, "Thiolite," has sulphur incorporated with it by digesting the treacle stage phenol-aldehyde resin with sulphur chloride, and removing the hydrochloric acid formed. Its physical properties are much like the normal resins, but claim is made for superior electrical resistance.

There might also be mentioned here some small French production of resins from acrolein. The cheap production of this by dehydration of glycerin and distillation enables a commercial product to be made either by simple polymerisation with a basic catalyst or condensation with phenol.

Lacquers.—Large amounts of air-drying or "cold" lacquer and stove drying or "hot" lacquer are used in the light metal trades. Ordinary phenol-aldehyde resins when baked do not adhere well to polished metal, are not flexible, and generally are too dark in colour and further darken in colour with exposure to light. They are not suitable for metal lacquering, but are suitable for papier maché and similar work. One of the Albertol modifications is said to produce a good lacquer. A new phenol-urea-formaldehyde lacquer removes entirely the faults of the phenol-aldehyde type, and seems to be a decided advance in protective lacquer work generally.

Pottery glazes.—Ordinary biscuit pottery can be glazed with phenol-aldehyde coloured enamels or glazes. They are baked at a low temperature compared with ordinary pottery glazes, but the goods resist water and heat sufficiently well for every ordinary purpose. Effects in colour and pattern can be obtained which are not possible by the usual pottery methods.

Insulating varnishes.—A solution of phenol-aldehyde resins in alcohol and acetone is largely used for treating taped or cotton-covered wires in electrical apparatus. After thorough drying, the formed coils are dipped in the varnish, air dried and then baked, and this process may be repeated to give a heavy coating.

The main advantage of this varnish is the perfect saturation which may be obtained, the high insulating value of the covering, and the fact that a mass of winding may be made into a strong, rigid, heatproof and waterproof mass which is not attacked by vermin or tropical insects.

THE COUMARONE RESINS

These are not synthetic compounds, but are mixed polymers consisting in the main of paracoumarone and paraindene. They are of interest as oil soluble varnish-making resins.

The commercial resins vary in softness, melting point and colour depending upon the proportion of coumarone indene and adventitious substances contained in the naphtha used as raw material and the care in manufacture. The supply of these resins was so variable and inferior at times that they earned a bad name amongst potential users of large quantities. The German qualities were generally inferior to the American, while a British product does not seem to exist. Light coloured, hard resins of consistent quality have been obtainable for some years. The tar distiller is only too well aware of the acid sludges obtained in washing light oils, and has tried to extract resins or other usable products from them

without success and without hope, for his beginnings are bad.

Good coumarone resins are made from the carefully fractionated distillate boiling between 160° and 185° C., free from benzene, toluene, xylenes, bases, tar acids and naphthalene. This fraction from various tar sources should be blended to obtain fairly uniform proportions of coumarone and indene with an average content around 30% of polymerisable substances. The washed distillate is dried with a wash of 1% of 76% sulphuric acid and then 3–5° of 96% sulphuric acid is added with violent circulation and efficient cooling. The reaction is exothermic, and special plant is necessary to keep the temperature down to 15° C. while maintaining reasonable speed of working. The tarry acid is separated, the polymerised oil is washed with soda and water, and the clean material is distilled until any naphthalene is cleared and a small amount of viscous polymerised oil distils. High vacuum is necessary, to keep the B.P. below 270° C. and maintain the pale colour of the resin which remains in the still.

The commercial coumarone resins are also made from less well-refined naphtha boiling between 150° and 190° C. A weaker acid is also used with a proportionately higher temperature, and other polymerising agents than sulphuric acid have been suggested by various patentees and are possibly used.

With the greatest care in manufacture, using the best quality materials, a certain amount of lower grade dark or soft resin is made, and it does not seem wise to use methods which cannot produce the pale, hard resins that are in greatest demand at the best price.

The commercial resins are graded according to colour and softening or melting point into five or six qualities. The hardest quality has a softening point of about 50° C. and a melting point of 135–150° C. by an agreed method, while the medium to soft grades soften at 25–40° C. and melt at 90–130° C. Some dark odorous resins, liquid to viscous at 15° C., are also sold.

Their solubility varies, but generally they are soluble in benzene, carbon tetrachloride and turpentine, not completely soluble in petroleum spirit, but soluble in mixture of this with coal tar naphthas or turpentine. In absolute alcohol they are generally soluble, but not in the weaker industrial spirit, although claims are made that alcohol soluble resins of this type are on the market.

The paint and varnish industry is probably the largest field for their use, and the harder qualities have been extensively used in America and Germany to replace, in whole or part, the more expensive natural resins and rosin esters in varnish and varnish paints. Coumarone resins are said to be more waterproof than many of the natural gums, and have been used in admixture with pitches in so-called "bituminous" paints. As an ingredient in rubber mixings, the medium to soft grades have been successful as softeners, promoting easy mixing. For overshoes, hose, mechanical goods and friction tapes the addition is said to be useful. For diluting gutta percha and balata there seems to be an opening as their dielectric constant is high, and they are waterproof and adhesive. Backeland suggested adding coumarone resins to the phenol-aldehyde type, but a

FIG. 6

Large six-platen press with synthetic resin paper sheets and moulded tubes under pressure.

better use seems to lie in their incorporation in "cold moulded" articles consisting of pitch, drying oils and fillers. In view of the increasing demand and failing supply of natural gums these coumarone resins are worth much more attention by chemists in the tar, paint, varnish, linoleum and mechanical rubber trades.

CARBAMIDE RESINS

Urea or carbamide is famous in chemical history as the first organic compound to be synthesised by Wöhler in 1828. It is now in the ranks of heavy chemicals made from atmospheric nitrogen, and is used as a manure. In 1889, Lüdy, and in 1896, Goldsmith, published data on the manufacture of resin-like bodies from carbamide and formaldehyde, noting that varying proportions and acid, neutral or alkaline conditions produced different products. Dixon and others also studied these reactions, but the first patent of commercial importance is that of H. John (E.P., 1920, 151,016), who used excess of formaldehyde with no catalyst. He obtained an adhesive substance as an intermediate product which became a transparent glass-like substance on heating, and he covers the use of thio-urea, benzoyl and acetyl ureas in place of carbamide. Pollak and Ripper have patented a series of methods of manufacturing such resins. A factory exists in Austria, and a British company is now formed with a capital of over £250,000 to work the patents, but at the moment the manufacture of these "Pollopas" resins does not amount to any large tonnage.

Some idea of the work done by Pollak and Ripper may be gathered from *Chemiker Zeitung*, Aug. 14 and 28, 1924, and it would seem, from what information is available, that the difficulties in producing large sheets of a clear glass-like product have not yet been overcome on the commercial scale. (Coloured glass and artificial amber rods which are machined to form useful articles, and a piece of plate glass 1 ft. square, were exhibited.)

The actual methods of manufacturing commercial products are very vaguely stated, but it is sufficient to know that on heating carbamide and formaldehyde in the presence of a basic salt, but in a solution about neutral to litmus, a condensation takes place and a watery or albumen-like solution may be obtained as a first stage. This solution is then polymerised by heat, and the hydrogen ion content may be varied to produce different types of colloid, as a second stage. When the water or salt solution is removed from this jelly-like mass considerable shrinkage takes place, and some ingenious methods have been proposed which are said to avoid cracks, bubbles and distortion, and so produce large pieces of perfect glass or moulded shapes for further machining. The cloudy and coloured resin material is more easily manufactured, and is worked up into fancy articles by turning and machining. (Some dress fabrics were exhibited which are decorated by a very ingenious method consisting of printing small beads of this clear glass or coloured resin in patterns. The beads are firmly attached to the silk, and cannot be washed off as they are baked in position, and the effect is pleasing and novel.)

Moulding powders are also made on similar lines to the phenol-aldehyde resin powders; but with the carbamide

resins very light or white mouldings may be obtained. The primary resin solution can be used in other ways, and auto-gelatinisation may be prevented by the addition of alkali salts of weak acids like borax or sodium acetate. Such a solution can be used for finishing textile materials by impregnating and drying out in dry steam and calendaring to form buckrams and similar stiff products. By varying the degree of such treatment, fabrics may be sized, glazed or linenised with a finish which does not wash out, and which produces a more desirable appearance.

According to Pollak, his resin is decomposed at 150° C., which is much below the charring point of the phenol-aldehyde resins. It is not quite waterproof, its specific gravity is given as 1.44, which is heavier than the phenol-aldehyde resins, and it apparently machines easily. Pollak states about Pollopas that "The new material also possesses special suitability for motor screens on account of the fact that it does not splinter." The material is very little more flexible than ordinary glass or the phenol-aldehyde resins according to figures given, but examination of the broken edges of specimens exhibited shows that these are not sharp, nor do they cut flesh like broken glass. Early samples of Pollopas were uneven in degree of refractive index and permeability to ultra-violet light, and in spite of the fact that it scratches fairly easily, hopes are entertained of making useful lenses and glass sheets permeable to ultra-violet rays. It is stated that the present production in Austria is of improved quality, and that it will find its place on the market.

THIOCARBAMIDE RESIN

A method of preparing this type of resin is described in E.P. 1926, 248,477, which, briefly stated, is to heat formaldehyde and thiocarbamide below 100° C., while passing a current of inert gas through the solution. Formic acid is thus removed, and a neutral watery solution of the resin provided suitable for polymerisation in commercial practice by the further application of heat. Moulding compositions have been made commercially by treating paper pulp, powders and colours with this solution. These mouldings can be produced in very light colours, and by using white pigments a fairly good white has been obtained. In this respect they excel the phenol-aldehyde resins. Their electrical insulating properties are not exceptionally good, and although quite sufficiently waterproof and resistant to soap and soda for domestic use, they do not compare favourably in such respects with the phenol-aldehyde resins. At 150° C. the thiocarbamide resins decompose with a very unpleasant smell. The watery resin solution can be used for stiffening and finishing textile fabrics without materially affecting their colour. Cotton goods can be given a linen finish, and filling materials made resistant to washing. Printed paper may be treated with the resin solution, and baked to form signs or glazed wall tiles having weatherproof properties, but they would not, of course, resist high temperature. A transparent product has not been put on the market, and the light colour of the resin seems to be the only advantage which it has over the phenol-aldehyde type of moulding powder.

GLYCEROL-PHTHALIC ANHYDRIDE RESINS

Watson Smith (J.S.C.I., 1901, 1075) gives the earliest practical data for the production of resins from glycerol and phthalic anhydride. Citric, tartaric, succinic and benzoic acids also form resin-like products with glycerol, while mixtures of these acids with phthalic anhydride have also been used. The research staff of the General Electric Co., of Schenectady, has developed this type of resin to the commercial stage. A large number of patents dating from 1914 in the names of Callahan, Arsem, Dawson and others cover various reactions and uses. The synthetic production of phthalic anhydride at a reasonable price now makes its use possible in industry.

The main use of this resin is as a substitute for shellac etc. for bonding mica flakes in the manufacture of micanite sheets and tubes for electrical insulation. Its special property is that it sticks firmly to a polished surface in both intermediate and final stages. Micanite thus bonded has a higher surface and volume resistance than shellac bonded mica, and the resin does not carbonise easily under an arc, like shellac or the phenol-aldehyde resins. Although it is light in colour, it is not of commercial interest in the making of moulding powder on account of the higher cost and long-baking time necessary to harden it compared with the phenol-aldehyde types. In fact, some types do not become infusible and insoluble on baking.

A typical resin is made by heating one part of glycerin with two parts of phthalic anhydride slowly up to 185° C., at which temperature it is held until distillation ceases.

The heating is continued at about 210° until samples show hardness without being sticky. This resin is soluble in acetone and other solvents, and may be made into lacquers.

To make it hard and insoluble the resin is further heated at 85-100° C. for several hours, and the temperature may then be raised for a further several hours. Rapid heating promotes considerable vesiculation, and the result is a useless pumice-like mass, instead of a transparent, machinable piece.

The sample of commercial Glyptol resin shown is easily soluble in acetone or mixture of acetone and alcohol, softens when heated to about 75° C., melts at 95°, and bubbles at 120°. Phthalic anhydride and acetic vapours are evolved on further heating and the residue is not easily carbonised. The solution in acetone and alcohol attacks copper slightly when applied as a lacquer and baked at 100° C. Two days' baking of this lacquer at 130° C. did not render it insoluble in acetone, and it still softened on heating to 100° C. This particular sample compares with a bleached shellac in physical properties and possible uses, and it does not quite agree in properties with published data for glycerol-phthalic anhydride resins.

Conclusions

The original search for synthetic varnish resins has resulted so far only in the modified phenol-aldehyde type called Albertols, the coumarone resins, and an insignificant supply of shellac substitutes of various composition and special application. The production of these

resins compared with consumption of the natural resins is quite small, and there is room for the discovery of something more satisfactory for varnish manufacture.

The side lines of research often result in discovery of more importance than the main object, and the commercial development of the phenol-aldehyde resins has provided new material and methods of production and new industries of considerable importance.

Over 90% of the synthetic resin manufactured is of the phenol-aldehyde type, and new application, modification, and increased output are frequently registered. Any successful competitive resin must show either cheaper material, more convenient application, cheaper method of manufacturing its products, greater resistance to heat or other destructive agents, or more pleasing appearance. Except for the light colour of the thio-carbamide resins, no competition is in sight. There is still a demand for a new synthetic material which will provide an electrical insulation whose electric strength is invariable under varying temperature, which is not damaged by an electric arc, which is easily worked and has all the other desirable properties demanded by the electrical engineer, and also for a transparent, colourless, synthetic material which will remove the danger of plate-glass windows on vehicles in a really satisfactory manner.

This mentions only two of the many demands for better material which follow the constant advance in quality of industrial products which, in turn, follows the rising standards of what we call civilisation. Such demands can only be met by continued scientific research on a more extended scale.

The author wishes to record his thanks to a number of individuals for help in the gathering of information, photographs and specimens, including the Danard Lacquer Co., Ltd., for specimens of Bukelite resins, moulding powders, finished products and lantern slides; Messrs. Birkbys, Ltd., for photographs, moulded products, moulding powders, and information; Mr. G. Ellison for samples of Tufnol products, resins, photographs, etc.; the British Thomson-Houston Co., Ltd., for sample of Glyptol resin; and Rubber Industries, Ltd., for samples of coumarone resins.

HYDRO-ELECTRIC DEVELOPMENT IN CANADA

The recent survey of the Pagan Falls, Gatineau river, indicates the possibility of a 135 ft. head; and 95 billion cb. ft. of storage at Bitobe dam. The power plant at Pagan Falls will be capable of developing 600,000 h.p. The Gatineau Power Co. (subsidiary of International Paper Co.) will commence delivery of power to the Ontario Provincial Hydro-Electric Commission on October 1, and reach a fixed maximum of 260,000 h.p. in 1931. The surplus power will be utilised by the Gatineau Mills of the Paper Corporation and Canada Cement Co., Hull, Quebec.

The West Kootenay Power & Light Co., Ltd., B.C. (subsidiary of Consolidated Smelting) showed a gross earning, for 1926, of \$1,660,668 as compared with \$1,041,125 in 1925, and \$683,516 in 1924. The surplus for 1926 amounted to \$449,733, as against only \$5238 in the preceding year.

SOCIETY OF CHEMICAL INDUSTRY OFFICIAL NOTICES

ANNUAL GENERAL MEETING, 1927

July 4 to 9

EXTENSION OF PERIOD FOR REDUCED RAILWAY FARES

Since the programme for the Annual Meeting was printed, the Railway Companies of Great Britain which agreed to issue tickets at the ordinary single fare and one third for the double journey to persons travelling to Edinburgh to attend the meeting have extended the validity of these tickets, and they will be available from Saturday, July 2, to Monday, July 11. These tickets will be obtainable at the time of booking on production of vouchers which will be supplied on application to Dr. W. T. H. Williamson, 13, George Square, Edinburgh.

It is urgently requested that all persons going by rail to Edinburgh for the meeting will take advantage of this concession.

If the holder of a return ticket at the reduced fare wishes to make use of it after the period for which it is available has expired, the excess payable will be the difference between the fare paid and the fare payable for an ordinary return or a tourist ticket, where such is available. This excess would have to be paid at an Edinburgh booking-office before commencing the return journey.

PROPOSED EXCURSION TO ST. ANDREWS ON SATURDAY, JULY 9

The train will leave the Waverley Station, Edinburgh, at 9.30 a.m., arriving at St. Andrews at 11.22 a.m.

A visit to the University, including the Chemical Laboratories, will be arranged for the afternoon, and the St. Andrews University Court has kindly offered to entertain the members to tea in the University Buildings.

The return train will leave St. Andrews at 5.35 p.m., arriving in Edinburgh at 7.26 p.m.

Members will also have an opportunity of visiting other places of historic interest in St. Andrews or of playing golf.

CHEMICAL ENGINEERING GROUP

A lunch for Members of the Chemical Engineering Group and their guests is being arranged for Wednesday, July 6, at 12.30 p.m., immediately after the meeting of the Group. The lunch will be held in the University Union, Park Place, Edinburgh. Price of tickets 5s., exclusive of wine and gratuities.

Members of the Society who are not Members of the Group are welcome to attend the lunch.

Charabancs will call at the University Union at 1.55 p.m. for those going to the Gasworks, and at 2.5 p.m. for those proceeding to King's Buildings. Application for tickets should be made immediately to Dr. W. T. H. Williamson at 13, George Square, Edinburgh.

BUREAU OF CHEMICAL ABSTRACTS

The following are the prices at which copies of the Index to British Chemical Abstracts, 1926, can be purchased:—

By members of the Chemical Society or the Society of Chemical Industry—5s. post free; by subscribers—10s. post free.

CALENDAR OF FORTHCOMING EVENTS

July 4 to 9. SOCIETY of CHEMICAL INDUSTRY. Forty-sixth Annual Meeting in Edinburgh. (See CHEM. AND IND., May 20, 1927, p. 464.)

July 4 to 8. SOCIETY OF CHEMICAL INDUSTRY, *Chemical Engineering Group*. Annual Meeting in Edinburgh. "Some aspects of the manufacture of fibrous cellulose," by Dr. J. L. A. Macdonald. A discussion will follow.

NATIONAL PHYSICAL LABORATORY

The annual visitation and inspection by the General Board of the National Physical Laboratory took place on June 24. Visitors were received by Sir Ernest Rutherford, Sir Richard Glazebrook and Sir Joseph Petavel. All the different departments of the Laboratory—*aerodynamics, engineering, metallurgy, the William Froude national tank, metrology, physics, optics and electricity*—were thrown open for the occasion, and about 200 exhibits representative of researches and investigations, completed or in course of completion at the Laboratory, were made available for inspection by visitors. In the Engineering Department the results of fatigue tests on single-metallic crystals were shown. An ordinary piece of metal consists of a multitude of small crystals (about 1,000,000,000 to a cubic inch). In each single crystal the atoms are arranged throughout according to a perfectly regular geometrical pattern, but the effect of this regularity is lost in an ordinary piece of metal owing to the different orientations of the small crystals making up the sample. In recent years methods for producing single crystals of certain metals, several inches long, have been developed. Such crystals are made in the Laboratory, and by submitting these to stresses applied in various ways and studying the resulting slip bands and changes of shape, considerable advance has been made in correlating the manner of fracture of metals with the planes of atoms in the crystals. Until quite recently the strength of engineering materials at high temperatures was obtained by breaking a test piece at the specified temperature, the test lasting a few minutes only. Recent investigations have shown that metals and alloys under a constant tensile load at high temperatures gradually increase in length and finally fail after a period often extending over some months. With newly-designed methods of testing, an endeavour is made to find the maximum loads at different temperatures; such materials will stand for many years when the loads are continuously applied. Such maximum load is, for any temperature, termed the "limiting creep load." Thus a nickel-chromium alloy having a breaking strength, as usually determined, of 18 tons per square inch at 800° C. broke in 37 days at that temperature under a *continuously applied* load of 2 tons per square inch. Investigations of this nature dealing with "Armco" iron, carbon steels and cast steel have been completed at the Laboratory, and the results are now in the press. Similar investigations dealing with boiler tube steels, normalised and heat-treated carbon steel, 3% nickel steel, cast and forged steels, special high-temperature steels, and new alloys containing nickel and chromium as a base, were shown in progress.

All the resources of modern science, from high-frequency induction furnaces to X-ray analysis and the ultra-violet spectrograph are employed in investigations relating to the production of metals and alloys shown in the Metallurgy Department. Progress in the design of gas, oil and petrol engines depends upon the use of increasingly higher temperatures and pressures, and new materials to withstand the imposed increasingly severer conditions are called for. Alloys are melted experimentally in a high-frequency induction electric furnace either in a vacuum or a controlled atmosphere, and are then cast, forged and rolled. Materials available commercially for the construction of crucibles capable of withstanding not only the high temperatures, but also the great chemical activities of the hot poured metals, do not meet all requirements, and investigations at the Laboratory have resulted in the production of special refractories suitable for these purposes. The casting, pressing and extrusion of these special refractories was demonstrated. Partly as the result of the success achieved in the production of these materials, it has been found possible to prepare very pure iron, chromium, manganese, silicon and beryllium, all of considerably higher purity than has previously been attained anywhere.

Balances employed in the standardisation of weights were exhibited in the Metrology Department. Weights used for scientific purposes are customarily verified to an accuracy of 1 part in 1,000,000, but in special cases even greater accuracy can be obtained. Experimental sets of weights being tested for stability, hardness and resistance to corrosion were exhibited. The tape bench used for the verification of standard tapes used in geodetic surveys has been found to have lengthened by nearly $\frac{1}{4}$ in. since it was built in 1908. Comparators capable of detecting differences of length of $1/1,000,000$ in. were exhibited.

The new standard "Shortt" clock, now used as the standard reference clock at Greenwich Observatory, was shown. This clock, which is free of escapement drive, comprises two pendulums, a master and a slave, working synchronously and maintained electrically. The former is of invar steel of zero coefficient of expansion, suspended by a strip of ellinvar of zero elasticity, and swings in an atmosphere of only 1-in. mercury pressure.

In the Physics Department a determination of the heat of combustion of carbon monoxide is being undertaken. The apparatus being employed, utilising the method of continuous flow calorimetry, was shown. A novel method for the measurement of flame temperatures has been developed in the department. The image of the tungsten sphere of a "pointolite" lamp is focussed through the flame on to a spectroscope. A sodium salt is introduced into the flame, and if the temperature of the flame is greater than that of the tungsten sphere, bright sodium lines show up on a continuous spectrum background. If the temperature is lower, reversal of the sodium lines takes place, the lines appearing dark. By careful adjustment of the temperature of the tungsten sphere, a point is reached at which all trace of either bright or dark lines disappears. This balance can be effected to within a few degrees. The temperature of the tungsten filament is then

determined by an optical pyrometer. A valve-controlled high-frequency furnace employed in an accurate determination of the melting point of palladium, and using a current of about 150 amps. in the oscillatory circuit at a frequency of about 1,000,000 cycles per sec. was shown. The department assists in the work of the X-ray and radium protection committee, established in 1921, by making measurements of the lead equivalent of materials used for X-ray protection, and by inspecting equipments. Plants used in determining the lead equivalents of such materials at voltages up to 100,000 and 200,000 volts were exhibited. Representative samples of protective materials, including heavy plaster slabs and cement blocks used in the construction of X-ray rooms, were also shown.

The subject of colour measurement is of considerable commercial importance in the dyeing, paint and varnish, and many other industries. Work carried out at the Laboratory has now rendered possible the introduction of scientific methods of colour measurement in place of the empirical and unrelated methods on which technical colour workers have had to rely in the past. The colorimeter developed in the Laboratory was amongst the exhibits in the Optics Department.

SOCIETY OF GLASS TECHNOLOGY

The one-hundredth meeting of the Society of Glass Technology was held in Sheffield on Wednesday, June 15, the President, Mr. Walter Butterworth, Sen., M.A., in the chair. Sir W. H. Hadow, C.B.E., D.Mus., LL.D., Vice-Chancellor of the University of Sheffield, was present and congratulated the Society on reaching its one-hundredth meeting.

A paper entitled "Gaseous fuels for furnace heating" was presented by Mr. R. Wiggington, B.Sc.

The chief gaseous fuel is producer gas, made by the partial combustion of coal (or coke) in an air-steam blast. Considerable variation in composition may be obtained by modifying the ratio of air to steam. Increasing the steam causes the partial replacement of carbon monoxide by hydrogen, and of nitrogen by carbon dioxide. A moderate use of steam improves the gas, but a further increase is disadvantageous. In a bunsen flame, the flame speed determines the back-firing tendency and the height of the inner cone. Hydrogen will thus give a shorter flame than carbon monoxide or methane.

In a non-aerated jet flame, on the other hand, the flame length depends chiefly on the air requirement. Hydrogen and carbon monoxide, each needing $2\frac{1}{2}$ times their own volume of air, will give equal jet flames, while methane, needing 10 volumes of air, will have a flame 4 times as long as either. Reduction of the oxygen in the atmosphere will cause a lengthening of the flame, which will finally leave the burner top and float about just before extinction.

The flame in a furnace may be regarded as a jet flame modified by turbulence to something approaching a bunsen flame. Hydrogen will still give a shorter flame than carbon monoxide in such circumstances. A long flame is generally preferred to give uniform heating.

Hydrogen more than other gases is liable to undergo flameless catalytic "surface combustion" in contact

with red hot brickwork. This (in ordinary furnace) is undesirable, as it leads to non-uniform heating and greater wear and tear of the refractories.

Gas rich in carbon monoxide is to be preferred on account of its longer flame, greater radiating power, and smaller liability to surface combustion. Uniformity in the gas (or at all events, absence of accidental variations) is obviously also very desirable, apart from the actual composition. These ends can only be secured by proper control over the blast saturation temperature of the producer; a thermometer in the blast pipe, or some more elaborate equivalent, is essential. Some form of positive blower is much easier to control than the usual steam jet. Sufficient steam to minimise clinker trouble must be used.

ROYAL PHOTOGRAPHIC SOCIETY Scientific and Technical Group

The Royal Photographic Society of Great Britain will hold its 72nd Annual Exhibition in September and October, 1927. This is the most representative exhibition of photographic work in the world, and comprises the recent achievements of photography, both pure and applied. It is desired to make the Scientific and Technical Section as representative as possible, and with this end in view exhibits are invited, which may comprise apparatus, models, prints, diagrams, transparencies, or any other form of record illustrating the applications of the photographic method to biology, botany, mineralogy, microscopy, geography, geology, spectroscopy, photometry, engineering, colorimetry, textiles, etc. Those who have material at their disposal suitable for exhibition will serve the best interests of photography if they will send their exhibits, before August 13, 1927, addressed to the Royal Photographic Society, 35, Russell Square, W.C.1. All communications should be addressed to the Hon. Secretary of the Scientific and Technical Group, Mr. Olaf Bloch, 35, Russell Square, W.C.1.

CANADIAN EXPLOSIVES

The annual report of the Explosives Division of the Dominion of Canada for the calendar year 1926 shows a net increase of two factories operating over 1925. There was no serious accident in manufacture, those arising being due to burns. The production for the year was as follows:—

Class I.	Gunpowder	...	383,543 lb.
„ II.	Nitrate mixture	...	1,167,773 „
„ III.	Nitro-compounds	...	34,350,210 „
„ IV.	Chlorate mixtures	...	133,400 „
„ V.	Fulminate, Div. I.	...	94,508 „
„ VI.	Ammunition	...	Not fully disclosed.
„ VII.	Fireworks	...	Approximate value, \$185,000.

There was an increase of about 4% in the blasting explosive classes, as compared with the output of 1925. The chief explosive materials imported were for re-manufacture, and consisted of nitro-compounds for explosive factories 111,890 lb., nitrocellulose 324,950 lb. Nitrocellulose for lacquers etc. amounted to 388,530 lb. Propellants 116,415 lb., Cordeau-Bickford fuse 275,688 ft., and fireworks 332,000 lb., were the chief items.

CORRESPONDENCE ASBESTOS FIBRES

SIR,—I have read through the article, "The characteristics and properties of the main types of asbestos fibres," in the issue of June 11, with considerable interest, as it is seldom that there is any reference in the technical press to this increasingly important industry.

There are several points, however, particularly references to the amphibole group, which I think it would be difficult to corroborate.

It is mentioned that the individual fibres of crocidolite (*i.e.*, South African Blue) are not so strong as the white chrysotile. This fact is referred to again in the concluding paragraph, where it is stated that "weight for weight, a chrysotile yarn is much stronger than crocidolite." It is my experience that the reverse of this is the case, and the results of tests made over long periods show that a blue asbestos yarn (crocidolite) is at least 50% stronger than a white asbestos (chrysotile) yarn of the same weight. In support of this contention I refer to a memorandum published in 1926, entitled "Asbestos with special reference to Canada," issued by the Natural Resources Intelligence Service, Canadian Department of the Interior, Ottawa, where it states that the strength of crocidolite is higher than chrysotile.

In referring to amosite the subject is dismissed lightly in a few words. I am afraid, however, that the author is not fully conversant with the position regarding amosite as it is to-day. This is the newest type of asbestiform mineral, and while these remarks may have been applicable to the mineral mined at first, yet this defect has been largely remedied with the material now being produced, for which a large and increasing market is being found.

Further, it is stated that the percentage of combined water in crocidolite asbestos varies from 4% to 10%. For these figures I can find no corroboration, either in my own tests or from reference to reports of the Department of Mines and Industries of The Union of South African Government. It can be stated that the maximum percentage of combined water as measured by the ignition loss in crocidolite and amosite is 4%. While the hypothesis that high combined water content is indicative of increased strength and flexibility may be true in the case of chrysotile, it is certainly not true in the case of crocidolite and amosite, for it is found that in the best grades of spinning fibres this figure falls to about 1%, whereas in the lower grades this figure rises to between 2% and 3%.

The fixing of 200° C. as the safe temperature of use for crocidolite is far too low, for the author's own figures in Table III quote 300° C. as producing no deterioration, and 400° C. as very little. Blue asbestos to-day is being freely used to the exclusion of all other materials for insulating surfaces maintained at temperatures as high as 500° C.

It is to be noted that the author definitely states that boiler mattresses made of crocidolite are more efficient than similar mattresses made of chrysotile. This, of course, is now generally accepted.

It is difficult to find corroboration for the author's statements that blue asbestos "is comparatively unstable" and "is liable to oxidise." Conditions prevailing

during the manufacture and use of asbestos cement sheets, for instance, are surely such as would produce oxidation, yet blue asbestos is being extensively used to produce a slate of great strength and durability.

Yours faithfully,

Chingford, E.4

A. J. DUNK

CLEANING OF COAL

SIR,—Prof. Louis' Messel Memorial Contribution dealing with the cleaning of coal will have been studied with interest by a large number of readers, and it deserves to provoke a useful discussion on this most opportune subject.

The difficulty is rightly emphasised by the author of de-watering in an economical way the sludge resulting from wet-cleaning of coal and the froth obtained by the flotation method. Considerable attention has been given to this point on the Continent, and as a result of very careful researches a type of filter has been designed by the Wolf Co. which is giving satisfactory results. A number of collieries in the Westphalian area are using this filter on washery sludge and on flotation coal, and the Dutch State Mines at Limburg, in Holland, have no less than 20 machines working on froth floated fine coal.

As regards the size of coal that can usefully be dealt with on a concentrating table, Prof. Louis infers that "the maximum is at $\frac{1}{2}$ in." Coal up to 1 in. is to-day being successfully wet-cleaned in this country on "Overstrom" coal-washing tables.

In the penultimate paragraph it is stated that the principle of difference in elasticity has been used in the Berrisford separator. Does not the Berrisford separator depend for its action on the difference of frictional resistance between coal and dirt sliding over a polished surface?—Yours, etc.,

HUNTINGTON, HEBERLEIN & CO., LTD.

London, E.C.4

A.S.L.I.B. DIRECTORY

SIR,—May I be allowed through the medium of the press to offer my thanks to all those who have kindly responded to my request for information in connection with the preparation of the Directory of Sources of Specialised Information, and at the same time beg those who could assist but have not yet written to me to do so at once as we are fast approaching the close of our work. I should especially like to be able to include some more collections in the possession of private individuals. I am, Sir, etc.,

G. F. BARWICK,
Secretary

Association of Special Libraries and
Information Bureaux, London, W.C.

AN ENQUIRY

An inquirer will be glad to receive information as to the names of some firms who can supply powdered metals 200 mesh to dust. Replies should be addressed to The Editor, CHEMISTRY AND INDUSTRY, 46-47, Finsbury Square, E.C.

PERSONAL AND OTHER ITEMS

The degree of LL.D. was conferred on the Rt. Hon. Sir Alfred Mond, Bart., M.P., at a graduation ceremony held at St. Andrews on June 28.

Mr. G. Le M. Mander, of the firm of Mander Bros., paint manufacturers, of Wolverhampton, has been adopted by the East Wolverhampton Liberal Council as prospective candidate, Mr. G. R. Thorne, M.P., having decided not to stand at the next General Election.

The Rt. Hon. Sir Alfred Mond, Bart., M.P., has resigned from the Board and the chairmanship of the Magadi Soda Co., Ltd., and Sir John Brunner has joined the Board and accepted the chairmanship. Lieut.-Colonel G. P. Pollitt, D.S.O., has been appointed to the Board.

Third Census of Production (Cement Trade)

Particulars are given below of the values of the output returned for the years 1924 and 1907 for the cement trade. The particulars given for 1924 relate to works in Great Britain only, and those for 1907 to the United Kingdom as a whole. The output in Ireland for that year was not sufficient to disturb comparisons:—

Products	1924		1907	
	Quantity Tons	Selling Value £	Quantity Tons	Selling Value £
Cement for building and engineering purposes ..	3,143,000	6,705,000	2,877,000	3,139,000
Chalk, prepared (including whitening) ..	80,000	147,000	—	70,000
Lime —				
White lime ..		46,000	—	19,000
Hydraulic and other lime ..		95,000		61,000
Casks (not included above in value of goods) ..		402,000		21,000
Quarry products sold ..		36,000	—	—
All other products ..		220,000	—	125,000
Total value ..		7,651,000	—	3,735,000

The quantity of cement manufactured in 1924 showed an increase of about 9% over the output in 1907, whilst the average value at works increased from about 24s. per ton in 1907 to 43s. per ton in 1924, or 79%. In both years manufacturers were instructed to exclude from the values to be stated for their products the value of returnable casks or cases. In 1924 exports of calcareous cement amounted to 651,000 t., valued at £1,609,000, or approximately 49s. per ton f.o.b., and net imports to 160,000 t., valued at £117,000 c.i.f., or an average of 52s. per ton. About 21% of the total quantity of cement made in 1924 was exported. In 1907 the cement exported, 764,000 t., was nearly 26½% of the quantity made, and in comparing 1924 with 1907 it must be remembered that 78,000 t. of the 1924 exports was consigned to the Irish Free State, shipments to which were not classed as exports in 1907. The amount available in Great Britain in 1924 appears to have been greater than in 1907 by roughly 500,000 t. The net output of the works in the industry in 1924 amounted to £4,679,000, and the net output per person employed was about £363 in 1924 and £132 in 1907. The cost of materials per ton of cement produced was 53% greater in 1924 than in 1907, and products other than cement were relatively more important in the later year. The aggregate cost of materials fell from about 48% of the total value of output in 1907 to about 39% in 1924. In this connexion it may be noted that,

per head of the aggregate number employed, the output of cement was 194 tons in 1907 and 244 tons in 1924. The larger out-turn of cement per head was due doubtless to the more general employment of rotary kilns.

In 1907 the number of persons employed in the industry was 14,819, and in 1924 the number totalled 12,874. The total capacity of the engines at the cement works and quarries in the industry was 90,256 h.p. in 1924, of which nearly 20% was in reserve or idle, compared with 60,079 h.p. in 1907. The capacity of electric generators at cement works in 1924 was 43,700 kw., and in 1907, 6685 kw.

Spanish Potash Production

A Spanish ministerial decree fixes the production of potash salts in Spain at a maximum of 60,000 tons and a minimum of 15,000 tons, the content of potassium chloride being 80% in both cases. Not more than 25% of the total output may be exported.

Chemical Employment in the United States

According to the U.S. Bureau of Labour Statistics, the number of pay rolls in the U.S. chemical industry during December decreased by less than 0.5%, compared with November. The number in the fertiliser industries fell by 11%, and in the petroleum refining industries by 0.6%, whereas there was an increase of 0.4% in the chemical industry. A total of 283 establishments manufacturing chemical and allied products reported 90,128 persons on the pay roll in December (91,581 in November), the distribution being: chemical industries, 29,458 (29,586); fertilisers, 7811 (8806), and petroleum refining, 52,859 (53,189).

Tin Poisoning

Poisoning by tin or its salts is a very rare occurrence in industry; in fact, only three cases of alleged poisoning appear to be recorded in literature. One case (*J. Ind. Hyg.*, February, 1927) was of a German, aged 66, who had been for ten years occupied in mixing a solution of tin tetrachloride in hydrochloric acid for use in the manufacture of silk. The arrangement for mixing was crude, but although highly irritating fumes were evolved, the worker was but little inconvenienced by them. Unusual symptoms were shown which suggested a diagnosis of neuritis. Traces of tin were found in the urine and faeces on two occasions, but on another no tin was found. The conclusion was reached that it does not seem reasonable to attribute poisonous properties to tin while only three cases of alleged poisoning can be discovered in the literature, and until other cases are added, a verdict of "not proven" must be given.

Italian Essential Oils

In consequence of the action of the United States Customs in regard to the admission of Italian essential oils, the Italian Minister of National Economy has issued an order providing that henceforth samples for analysis must be submitted of all consignments of essential oils destined for export. As a result, the Chamber of Commerce of Messina, acting in conjunction with the Camera Agrumaria and the Experimental Station, now refuses to grant an export permit to consignments of essential oils unless accompanied by a certificate of analysis. A control laboratory is to be opened shortly in Milan.

REVIEWS

INDICATORS, THEIR USE IN QUANTITATIVE ANALYSIS AND IN THE COLORIMETRIC DETERMINATION OF HYDROGEN-ION CONCENTRATION. By Dr. I. M. KOLTHOFF, translated from the 2nd German edition, revised and enlarged, by N. HOWELL FURMAN, Ph.D. Pp. xii + 269. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, 1926. Price 17s.

This translation is based on the second German edition of Kolthoff's book, which has also appeared in a French version by M. Vellinger (*CHEM. AND IND.*, 1926, 45, 247). Reference may be made to this review for a further account. The book, as its title implies, deals only with colorimetric determinations; potentiometric determinations by the hydrogen electrode etc. are described in the supplementary volume on "Electrometric titrations," by the same author (see *CHEM. AND IND.*, 1926, 45, 912), and in M. Kopaczewski's book.

The theoretical part is based on the classical theory of hydron and hydroxylion equilibria, as applied particularly to weak acids and bases which obey the law of concentration action (dilution law). The numerous and useful computations which have been rendered possible by this theory are clearly expounded. The full experimental directions for the use of each indicator or test paper are to a considerable extent the result of the author's research. One could have wished for a more adequate treatment of sparingly soluble acids and salts (the solubility product). Also the acidities and alkalinities due to strong acids and alkalis are hardly referred to, and not tabulated. It is thus evident that this short review calls merely for an enlargement of scope, and is written with full appreciation of a most excellent practical text book.

E. B. R. PRIDEAUX

CHEMICAL SYNONYMS AND TRADE NAMES: A DICTIONARY AND COMMERCIAL HANDBOOK. By W. GARDNER. Third edition, revised and much enlarged. Pp. 355. London: Crosby Lockwood & Son, 1926. Price 30s.

The short time within which this book has reached its third edition indicates that it fills a real need. A considerable improvement was shown in the second edition, but the third edition shows a still further advance, as the number of definitions and cross-references in the dictionary has been increased by 3000 to 20,000, and the number of pages from 327 to 355, whilst much of the matter has been rewritten and improved. Indeed, the progressive enlargement of the scope, and the amount of information given in the references, make one wonder whether the work may not eventually blossom out as an encyclopædia. However, as it stands, the book is most comprehensive, the definitions are concise and informative, and the volume will be useful to everyone who has to do with chemical and commercial products in name or fact. Both author and publishers deserve praise for the new edition, which is now free from the supplement placed at the end of the second edition, the new matter having been incorporated in the body of the book. The production conforms to the high standard set by previous editions.

PARLIAMENTARY NEWS

Sugar Beet Industry

In answer to Mr. Stephen, Sir J. Gilmour said it was not yet possible to give any figures for the current season, but from information received by him from the two companies who manufacture sugar from home-grown beet in Scotland, the number of persons who supplied beet of the 1926 crop was 1051. The amount of subsidies paid to the companies in respect of the 1926 crop was £71,421 8s. 5d.; under the British Sugar Subsidy Act, no subsidy was paid direct to growers. In 1926 the area under crop was 3649 acres, and it is estimated that in 1927 there will be 12,500 acres under crop. The total output for Scotland from the 1926 crop was 71,971½ cwt. of sugar, and 16,705½ cwt. of molasses. The Government had assisted the development of two factories in Scotland by way of guarantees under the Trade Facilities Act. The Orchard Sugar Co., Ltd., had received a guarantee of £150,000 in respect of the Greenock factory, and a guarantee of £865,000 had been given to the Second Anglo-Scottish Beet Sugar Corporation, of which approximately £250,000 was allocated to the cost of the Cupar factory. June 21.

British Celanese Ltd.

Mr. McNeill informed Mr. W. Thorne that the Government had recently sold 500,000 preference shares, the remainder of its holding in the British Celanese Company, at 20s. per share. June 22.

Fuel Research

The Duchess of Atholl informed Mr. Hardie that no entirely new process of coal treatment had been developed at the Fuel Research Station to the point of commercial application. The general policy, subject to considerations of public interest, was to place the results of Government research at the disposal of all responsible persons or firms in this country engaged in the industry or industries concerned. In the case of many improvements to processes of coal treatment now worked on the large scale by gas undertakings in this country, which have been suggested as the result of work at the Fuel Research Station, the results have been made generally available without charge. The general object of most fuel research, as well as other research undertaken by the Department of Scientific and Industrial Research, was not so much to develop commercial processes as to provide fundamental data on which commercial processes could be developed by private enterprise. June 23.

Research in the Sugar Industry

In reply to Mr. Kelly, Earl Winterton said he was aware that in 1925-26 India imported 738,224 tons of refined sugar as against 670,965 tons in the preceding year. A scheme for the establishment of a sugar research institute was laid before the Government of India some years ago. The Government of India intimated last year that they did not know when they would be in a position to give effect to the scheme, which involved a heavy outlay. A great deal was being done now to increase the production of sugar in India, and also to improve the quality of the sugar grown. June 27.

Cement

Sir K. Wood informed Mr. Dennison that on an average about 2½ tons of cement was required in the

construction of a brick subsidy house, in cases where cement was used. He had no information as to the quantity of foreign cement used for this purpose. According to recent quotations in Glasgow, the price of Scottish cement (blast furnace) was 47s. 6d. per ton, as compared with 47s. for foreign cement. Section 10 of the Housing (Financial Provisions) Act, 1924, provides that, in approving proposals for the construction of houses, the Minister of Health shall not impose any conditions which would prevent the materials required being purchased in the cheapest market at home or abroad. Local authorities have been urged by the Government to arrange that all contracts for or incidental to works carried out by them should, in the absence of special circumstances, be placed in this country. June 27.

COMPANY NEWS

MAGADI SODA CO., LTD.

A loss of £35,498 is reported for the year 1926, compared with a profit of £23,937 for 1925. This adverse result is attributed to production being discontinued in the early part of February, 1926, in order to clear old stocks. During this period of cessation the plant was overhauled and improvements effected, the benefit being apparent since production recommenced in August, 1926. The sum of £6680 is available for distribution, which will enable interest at 1% (which with 5% already distributed makes 6%) to be paid to debenture holders, leaving £1681 to pay a dividend at the rate of 0.768% to the first preference shareholders. Production and sales for 1927 have so far been satisfactory. Sir Alfred Mond, M.P., has resigned from the Board and the chairmanship, owing to his many other engagements, and Sir John Brunner has joined the Board and accepted the chairmanship. Mr. Arthur Colegate has resigned from the Board, and Mr. A. R. Gregory has been elected in his place. The directors have also appointed Mr. Duncan Marsh and Lieut.-Colonel G. P. Pollitt, D.S.O., to the Board.

ZINC CORPORATION, LTD.

The sixteenth ordinary general meeting was held on June 15, Sir Robert Horne, G.B.E., K.C., M.P. (chairman), presiding. He expressed deep regret at the death of the late chairman, Mr. F. A. Govett, who was chiefly responsible for the position in the mining world which the Corporation now held. His son, Mr. J. R. Govett, had been appointed a member of the Board, and Mr. W. S. Robinson had been elected managing director. The profit for 1926 amounted to £124,048, against £541,946 for 1925. A final dividend was declared of 4s. per share on the ordinary shares, making 7s., leaving £22,000 to be carried forward against £13,373 brought in. A year ago shareholders were advised to regard 1925 as a "peak" year, and not to expect a continuance of such profits in 1926. The decreased profits resulted from the loss of about a month's productive operation due to water shortage at Broken Hill and the reduction in metal prices. But for the former their ore output would have created a record for the company. The drop in the prices of metals had been serious, the difference between the average of 1925 and 1926 being no less than £4 15s. per ton as regards lead,

£2 2s. 4d. per ton for zinc, and 3·3293d. per ounce for silver. There had also been a further substantial fall, the differences between the average prices of 1925 and those ruling on the date of the meeting being no less than £11 6s. per ton of lead, £7 3s. 9d. per ton of zinc, and 5·6951d. per ounce silver. In 1926 production of lead and spelter exceeded the demand. The following figures show the world's production of lead and spelter in long tons:—*Lead*: 1914, 1,136,000; 1924, 1,301,501; 1925, 1,463,500; 1926, 1,538,500. *Spelter*: 1914, 864,300; 1924, 1,004,500; 1925, 1,128,500; 1926, 1,263,000. The chief work carried out at the mine at Broken Hill during the year was the sinking of the main shaft, and in 1927 the developments should be more productive from the point of view of opening up ore. On the metallurgical side, the work of the new plant had shown further progress during the year. The recovery of lead in lead concentrates had risen to approximately 92%, as against under 86·5% in the old plant, whilst the recovery of zinc in zinc concentrates was almost 80%, as against 50%. The company had joined with the British Metal Corporation and the Tanganyika Concessions in the formation of a company entitled the British (Non-Ferrous) Mining Corporation, Ltd., under the chairmanship of Sir Cecil Budd. This new company will be in a position to investigate and handle the mining proposals that are continually being brought to the three companies above-mentioned. In conclusion, the chairman said that although the immediate future could not give the same result as the years just past, the outlook for the Corporation appeared to be definitely favourable.

MINERALS SEPARATION LIMITED

A dividend has been declared of 10%, less tax, for 1926 (the same as for 1925), payable on June 30.

AMERICAN CYANAMID CO.

The usual quarterly dividend has been declared of $1\frac{1}{2}\%$ on the preferred stock, and a dividend of $1\frac{1}{2}\%$, plus $\frac{1}{2}\%$ extra, on the common stock.

PINCHIN, JOHNSON AND CO., LTD.

At an extraordinary general meeting of the ordinary shareholders, held on June 22, a resolution was passed to increase the share capital of the company to £1,350,000 by the creation of 250,000 additional £1 ordinary shares. This extra capital was required in order to acquire additional interests that would profitably and suitably fit in with the company's programme of development. For some time past the Board had been considering the question of applying its efforts to extending its activities in the ships' bottom and anti-fouling composition section of the paint trade, the field in that market being a very wide and extensive one. An agreement had been entered into whereby the company acquired the assets and goodwill of the Red Hand Compositions, Ltd., an old-established and successful company in this section of the trade. The business of the Red Hand Compositions, Ltd., will continue to operate as a separate trading unit, under the present efficient management. Only a small proportion of the additional shares to be created would be required to give effect to the agreement, leaving a considerable number of ordinary shares authorised but unissued, which in the near future would be applied for the direct benefit of the shareholders on such terms as the Board would eventually determine.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.—£6 15s. per ton. f.o.r. Special terms for contracts.
Bisulphite of Lime. £7 10s. per ton, packages extra.
Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
Copper Sulphate.—£25—£25 10s. per ton.
Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
Nickel Sulphate.—£38 per ton d/d.
Nickel Ammon. Sulphate.—£38 per ton d/d.
Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
Salammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic Sulphide, Yellow.—1s. 9d. per lb.
Barytes.—£3 10s.—£6 15s. per ton, according to quality.
Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
Carbon Bisulphide.—£20—£25 per ton, according to quantity.
Carbon Black.—5½d. per lb., ex wharf.
Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
Chromium Oxide, Green.—1s. 1d. per lb.
Diphenylguanidine.—3s. 9d. per lb.
Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.

Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals,—8d.—9d. per lb. Crude 60's, 2s. 3d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 4½d. per gal. Pale, 95%, 2s.—2s. 2d. per gal. Dark, 1s. 9d.—2s. 1d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 1s. 0½d.—1s. 1½d. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 8d.—2s. 0½d. per gal. Pure, 1s. 10d.—2s. 3½d. per gal.
 Xylol.—1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%,—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—8½d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 8½d.—9d. per gal., according to quality. Solvent 90/100, 1s. 2d.—1s. 11d. per gal. Solvent 95/100, 1s. 5d.—1s. 6d. per gal. Solvent 90/190, 1s. 1½d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals,—£11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—75s.—85s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.
 Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorbenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d.—8d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 4½d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—Cryst. £40—£43 per ton. Powder £44—£47 per ton. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 7½d.—1s. 8d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallic, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. pulv. 1s. 3½d.—1s. 5d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 9d.—2s. 11d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton; Powder £39 per ton, in 5-cwt. casks. Resublimed.—Lump 1s. per lb., Powder 1s. 3d. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. 6d. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—Crystal £24—£27 per ton, Powder £26—£29 per ton, according to quantity, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 3d.—2s. 6d. per lb. Potassium.—1s. 10d.—2s. 1d. per lb. Sodium.—2s. 1d.—2s. 4d. per lb. All spot.

Calcium Lactate.—1s. 3d.—1s. 5d. per lb.

Chloral Hydrate.—3s. 2d.—3s. 5d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7d. per lb., according to quantity.

Creosote Carbonate. 6s. per lb.

Ethers: Prices for Winchester quarts; dozen Winchester quarts; carboys or drums; and 10 cwt. lots respectively; 730—1s. 2½d.; 1s. 2d.; 1s. 1½d.; 1s. 0½d.; 720 tech.—1s. 5½d.; 1s. 5d.; 1s. 4½d.; 1s. 3½d.; 720 pur. (Aether P.B. 1914)—2s. 4d.; 2s. 3½d.; 2s. 3d.; 2s. 2d.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiaac Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ¼ lb., 9s. 6d. per doz.; ½ lb., 6s. 6d. per doz. 10 vols.—2s. 3d.—2s. 11d., according to quality and package.

Hydroquinone.—4s. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—4d. per lb., 20s.—22s. per cwt., according to quantity.

Magnesium Carbonate.—Light Commercial £31 per ton net.

Magnesium Oxide.—Light Commercial £02 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 6d. per lb. net. Synthetic detached crystals, 11s.—14s. 6d. per lb., according to quantity; Liquid (95%), 12s. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonol.—11s. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—3s. per lb.

Phenazone.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar) 100s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 2d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.

Resorcin.—4s. per lb. spot.

Saccharin.—55s. per lb., and lower in quantity.

Salol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C., 1911.—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s.—2s. 1d. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hypsulphite.—Photographic, £15 6s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—95s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonol.—7s. 6d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s.—2s. 2d. per lb.

Thymol, Puriss.—10s. 3d.—11s. 6d. per lb., according to quantity. Natural.—15s. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (ex Anethole).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 9d. per lb.

Ethyl Cinnamate.—7s. 6d. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. Geraniol (Pulmarosa).—17s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(ex Bois de Rose) 15s. per lb.—(ex Shui Oil) 10s. 6d. per lb. Linalyl Acetate.—(ex Bois de Rose) 18s. per lb.—(ex Shui Oil) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—32s. 6d. per lb. Safrol.—1s. 6d. per lb. Terpeneol.—1s. 6d. per lb. Vanillin.—17s.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. 1d. per lb. Bergamot.—28s. 6d. per lb. Bourbon Geranium.—14s. 6d. per lb. Camphor.—67s. 6d. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 3d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 1s. 11d. per lb., Ceylon, Pure, 1s. 9d. per lb. Clove, pure.—6s. per lb. Eucalyptus, 75/80%.—2s. 4d. per lb. Lavender.—Mont Blanc 38/40%, 21s. per lb. Lemon.—8s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz. Palma Rosa.—10s. 6d. per lb. Peppermint.—Wayne County, 18s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 6d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug. 20th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C.2, on July 7th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Du Pont de Nemours & Co. Catalysts etc. 15,717. June 13. (U.S., 12.6.26.)

Higgins. Carrying out chemical reactions at high temperatures. 16,245. June 18.

I.-G. Farbenind. Carrying out catalytic oxidations. 15,723. June 13. (Ger., 14.6.26.)

Kendall. Manufacture of concentrated stable gels. 15,941. June 15.

Kidde & Co. Detection of suspended matter in aeriform fluids. 15,863. June 14. (U.S., 17.6.26.)

Marks (Petroleum Process Co.). Treating fluids etc. 15,711. June 13.

Mielek. Continuous treatment of liquids with gases. 15,854. June 14. (Ger., 15.6.26.)

Piron. Distillation process. 15,698. June 13. (U.S., 27.7.26.)

Walker. Centrifugal mills. 15,657. June 13.

I.—Complete Specifications

30,808 (1925). Empson. Centrifugal filtering-apparatus. (271,916.)

9030 and 9932 (1926). Tinker. Drying apparatus. (272,316 and 272,319.)

14,782 (1926). Empson Centrifugals, Ltd., and Alexander. Centrifugal purifying and dehydrating apparatus. (272,339.)

20,404 (1926). Geigy A.-G. Mixing liquids for carrying out reactions and producing dispersion systems. (257,274.)

24,422 (1926). Parker. Centrifugal extractors. (272,368.)

*15,717 (1927). Du Pont de Nemours & Co. Catalysts and catalytic processes. (272,555.)

*15,723 (1927). I.-G. Farbenind. Carrying out catalytic oxidations in the gaseous or vapour state. (272,557.)

II.—Applications

Dunlop (McQuade). Carbonising coal. 15,796. June 14. I.-G. Farbenind. Manufacture of liquid hydrocarbons etc. 15,722. June 13. (Ger., 14.6.26.)

Johnson (I.-G. Farbenind.). Manufacture of liquid products from coal etc. 16,068. June 16. Production of hydrogen. 16,253. June 18.

Mills and Noble. Coal briquettes. 15,663. June 13.

N. V. Silica en Ovenbouw Mij. Coke ovens. 16,094. June 16. (Ger., 16.6.26.)

Sacchi. Production of hydrogen. 15,758. June 13.

Vercin f. Chem. Ind. Producing active carbons. 15,926. June 15. (Ger., 3.7.26.)

II.—Complete Specifications

6253 (1926). Foersterling. Manufacture of air gas. (248,770.)

6420 (1926). Standard Telephones & Cables, Ltd. (Western Electric Co.). Manufacture of granular carbon. (272,279.)

6811 (1926). Henshaw. Condensers for recovery of by-products in carbonisation of coal etc. (272,293.)

6949 (1926). Williams, and Minerals Separation, Ltd. Froth-flotation concentration of coal. (272,301.)

20,866 (1926). Svenska Akt. Mono. Gas-analysing apparatus. (257,609.)

26,227 (1926). Still. Distillation of solid fuels. (272,375.)

6878—9 (1927). Allgem. Ges. f. Chem. Ind. Converting high-boiling into low-boiling hydrocarbons. (271,042 and 272,433.)

*14,170 (1927). I.-G. Farbenind. Manufacture of hydrocarbons from mineral oils, tars, etc. (272,483.)

*14,767 (1927). Hellmann. Ovens for treating fuels. (272,493.)

*15,376 (1927). Comp. des Mines de Bruay. Distillation of fuels at low temperatures. (272,522.)

*15,386 (1927). Trautmann. Extraction of hydrocarbon oils from coal. (272,526.)

*15,525 (1927). I.-G. Farbenind. Destructive hydrogenation of carbonaceous materials. (272,538.)

*15,526 (1927). I.-G. Farbenind. Treatment of coal tars mineral oils, etc. (272,539.)

*15,722 (1927). I.-G. Farbenind. Manufacture of liquid hydrocarbons etc. from coal, tars, mineral oils, etc. (272,556.)

III.—Complete Specifications

*14,179 (1927). I.-G. Farbenind. See II.

*15,526 and 15,722 (1927). I.-G. Farbenind. See II.

IV.—Applications

Carpmael (I.-G. Farbenind.). Manufacture of compounds from indene and phenols. 15,865. June 14. Manufacture of condensation products of the aromatic series. 15,996. June 15. Manufacture of dyestuffs. 16,087. June 16.

Chem. Fabr. vorm. Schering. Manufacture of condensation products from alkylated phenols and ketones. 15,992. June 15. (Ger., 29.6.25.) 15,993—4 and 16,198. See XX.

I.-G. Farbenind. Production of metallic compounds of dyestuffs. 15,724. June 13. (Ger., 15.6.26.) Manufacture of dyestuffs. 15,967. June 15. (Ger., 15.6.26.) Production of dyestuffs. 16,172. June 17. (Ger., 17.6.26.)

Imray (I.-G. Farbenind.). Manufacture of naphthalene derivatives. 16,092. June 16.

IV. Complete Specifications

6020 (1926). I.-G. Farbenind. Manufacture of anthraquinone compounds. (248,759.)

10,159 (1926). British Dyestuffs Corp., Rodd, and Linch. Preparing triarylmethane dyes. (272,321.)

*13,509 (1927). I.-G. Farbenind. Production of anthraquinone derivatives. (272,469.)

*15,422 (1927). I.-G. Farbenind. Manufacture of compounds of the perylene series. (272,528.)

V. Applications

Bernard. Preparation of cellulose compounds. 15,812. June 14. (Fr., 24.6.26.)

Diehl and Huebner. Spinning artificial silk etc. 15,786. June 14.

Leuchs. Manufacturing artificial silk etc. from viscose. 16,264. June 18.

N.V. Nederlandsche Kunstzijdefabr. Manufacture of artificial textile products. 16,080. June 16. (Italy, 16.6.26.)

Ohsaka. Production of artificial silk. 15,704. June 13.

Textile et Filature Soc. Anon. Preparation of kapok etc. for spinning. 15,785. June 14. (Fr., 14.6.26.)

V.—Complete Specifications

*13,806 (1927). Du Pont Rayon Co. Manufacture of viscose. (272,475.)

*15,785 (1927). Textile et Filature Soc. Anon. Preparation of kapok etc. for spinning. (272,564.)

VI.—Application

I.-G. Farbenind. Dyeing textile goods. 16,093. June 16. (Ger., 18.6.26.)

VI.—Complete Specification

*14,178 (1927). I.-G. Farbenind. Production of dyeings on cellulose esters or ethers. (272,482.)

VII.—Applications

Austin and Bailey. 16,105. See XIII.

Johnson (I.-G. Farbenind.). Manufacture of calcium nitrate etc. 16,067. June 16. 16,253. See II.

Sacchi. 15,758. See II.

Uhde. Separating ammonia from gases etc. 15,984. June 15. (Ger., 15.6.26.) Synthesis of ammonia. 15,985. June 15. (Ger., 15.6.26.)

VII.—Complete Specifications

30,647 (1926). I.-G. Farbenind. Purification of alkali cyanide solutions. (262,456.)

30,881 (1926). I.-G. Farbenind. Production of sodium sulphide. (264,464.)

VIII.—Application

Port. Manufacture of splinterless glass. 15,736. June 13.

VIII.—Complete Specifications

29,473 (1926). Quartz & Silice. Manufacture of ceramic materials. (263,765.)

707 (1927). Soc. Anon. des Manuf. des Glaces et Prod. Chim. de St. Gobain. Glass. (264,490.)

IX.—Applications

Pickstone. Manufacture of cement mortar etc. 16,031. June 16.

Soc. Anon. La Trinidad. Manufacture of asphaltic etc. emulsions. 15,705. June 13. (Fr., 15.10.26.)

IX.—Complete Specifications

23,206 (1926). Hack. Material for roadways etc. (258,870.)

29,060 (1926). Okuri. Insulating compositions containing mica. (272,384.)

*13,961 (1927). Thompson. Concrete. (272,479.)

X. Applications

Barton. Manufacture of metallic sublimates. 15,897. June 15.

Canning & Co., Ltd., and Pope. Electroplating apparatus. 16,257. June 18.

Coles. Transmutation of metals. 15,653. June 13. Transparent metals. 15,654. June 13.

L.-G. Farbenind. Recovering metals from scrap. 15,753. June 13.

Jones. Reduction of non-ferrous oxides etc. 15,659. June 13.

Metallbank und Metallurgische Ges. Production of diffused layers on metals. 15,957. June 15. (Ger., 15.6.26.)

Norbury. Thermal treatment of silver alloys. 15,673. June 14.

Picard and Sulman. Extraction of tin etc. from ores. 15,665. June 13.

Turnbull. Galvanising baths. 15,777. June 14.

Verein. Stahlwerke. Manufacture of cast iron. 15,851. June 14. (Ger., 15.6.25.)

Wüst. Purifying pig iron. 16,155. June 17. (Ger., 17.7.26.)

X.—Complete Specifications

10,062 (1926). Beckinsale and Waterhouse. Lead alloys. (272,320.)

12,008 (1926). Tullis. Purifying aluminium and its alloys. (272,326.)

21,209 (1926). Grunwaldt. Removal of impurities from minerals etc. (258,246.)

*15,304 (1927). Moulin and Berger. Manufacture of zinc and zinc products. (272,517.)

XI.—Applications

Canning & Co., Ltd., and Pope. Electrolytic apparatus. 15,764. June 14. 16,257. *See* X.

Jackson (Burgess Laboratories). Dry cells. 15,744. June 13. Kelsen. Anode for electrolytic purposes etc. 15,754. June 13. (Austria, 11.6.26.)

Metallwerk Plansee Ges., and Schwarzkopf. Electric furnaces. 16,006. June 15. (Ger., 16.6.26.)

Silica Gel Corp. Electric storage batteries. 15,668. June 13. (U.S., 12.6.26.) Electric batteries. 15,872. June 14. (U.S., 15.6.26.)

XI.—Complete Specifications

13,366 (1926). Darimont. Double-fluid cells. (266,602.)

25,051 (1926). British Thomson-Houston Co., Ltd. Electric furnaces. (259,599.)

29,060 (1926). Okuri. *See* IX.

*15,121 (1927). British Thomson-Houston Co., Ltd. Treating filaments. (272,500.)

*15,668 (1927). Silica Gel Corp. Storage batteries. (272,550.)

*15,754 (1927). Kelsen. Anode for electrolytic purposes. (272,563.)

XII.—Complete Specifications

*15,203—4 (1927). Harvel Corp. Treating cashew-nut-shell oil. (273,509—10.)

XIII.—Applications

Austin. Production of white lead. 16,105. June 16. (U.S., 22.6.26.)

Carroll. Anticorrosive heat-resisting paint etc. 16,233. June 18.

Nobel Industries, Ltd. (Du Pont de Nemours & Co.). Coating compositions. 16,262. June 18.

Schmidt. 16,079. *See* XX.

XIV.—Applications

Johnson & Johnson (Great Britain). Ltd. (Johnson & Johnson). Manufacture of rubber emulsion. 16,000. June 15.

Synd. Franco-Néerlandais. Regeneration of rubber. 16,028. June 16. (Fr., 25.8.26.)

XIV.—Complete Specification

27,490 (1926). Goodrich. Thermo-plastic derivatives of rubber. (260,637.)

XV.—Applications

Jaroslav's Erste Glimmerwaren-Fabr. Manufacturing plastic masses from casein etc. 16,162. June 17. (Ger., 17.6.26.)

Johnson (L.-G. Farbenind.). Manufacture of tanning-agents. 16,254. June 18.

XV.—Complete Specification

15,550 (1927). Keleti. *See* XXIII.

XVII.—Applications

Elektro-Osmose A.-G. Purifying sugar solution. 16,095. June 16. (Ger., 16.6.26.)

Ellis (Chem. Works formerly Sandoz). Oxidation of aldoses. 16,187. June 17.

Marks (Corn Products Refining Co.). Manufacture of dextrose. 15,977. June 15.

Mautner. Increasing stability of starch, sugar, etc. 15,980. June 15.

Nouvelles Industries Chimiques. Recovery of nitrogen and acetone from molasses etc. 15,726. June 13. (Belg., 21.9.26.)

XVII.—Complete Specification

6346 (1926). Stern. Making starch products. (272,274.)

XIX.—Applications

Carpmael (L.-G. Farbenind.). Conserving foods etc. 15,864. June 14.

Ebor Trading Co., Ltd., and Greville. Treatment of cereals. 16,221. June 18.

Greville. Manufacture of wheat flour etc. 15,950. June 15.

Miles and Reilly. Preparation of vegetable food. 16,185. June 17. (U.S., 8.7.26.)

XIX.—Complete Specifications

26,645 (1926). Agopian. Production of concentrated preparations of vitamine C. (272,376.)

*13,504 (1927). Zierer. Preparation of yoghurt milk etc. (272,468.)

XX.—Applications

Bertsch, and Böhme A.-G. Rendering alcohols soluble. 15,954. June 14. (Ger., 15.6.26.)

Carpmael (L.-G. Farbenind.). 15,865 and 15,996. *See* IV.

Chem. Fabr. vorm. Schering. Manufacture of mixed alkaloid salts. 15,766. June 14. (Ger., 26.6.26.)

Manufacture of alkylisopropylphenols etc. 15,993—4. June 15. (Ger., 29.6.26.)

Manufacture of alkylated phenols etc. 16,198. June 17. (Ger., 14.7.26.) 15,992. *See* IV.

Consort. f. Elektrochem. Ind. Manufacture of acetic anhydride. 15,966 and 16,179. June 15 and 17. (Ger., 16.6.26 and 17.6.26.)

Ellis (Chem. Works formerly Sandoz). 16,187. *See* XVII.

Johnson (L.-G. Farbenind.). Manufacture of organic compounds. 16,252. June 18.

Nouvelles Industries Chimiques. 15,726. See XVII.

Schmidt. Production of artificial materials from condensation products of urea etc. 16,079. June 16. (Ger., 8.12.26.)

Stephens (Wülfing). Manufacture of primary propyl ester of 2-phenylquinoline-4-carboxylic acid. 16,191. June 17.

Tcherniac. Manufacture of alkyl ethers of phenolic amides. 15,695. June 13.

Verley. Substituting alkyl group in the aromatic nucleus. 16,097. June 16. (Fr., 31.3.27.)

Wecker. Manufacture of esters of fatty acids etc. 15,681. June 13. (Ger., 23.6.26.)

XXI.—Applications

Devienne. Toning etc. photographic prints. 15,968. June 15. (Fr., 21.6.26.)

Harding, Ltd., and Leuch. Manufacture of photographic material. 16,184. June 17.

Liguoro. Production of photographic films. 15,979. June 15.

XXIII.—Complete Specifications

*15,550 (1927). Keleti. Producing a disinfectant, tanning agent, etc. (272,541.)

*15,572 (1927). Boehringer Sohn. Production of disinfecting agents. (272,543.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—*Australia*: Crockery, druggists' sundries (Commercial Bureau, Australia House, Strand, W.C.2, Ref. No. 454). *Belgium*: Waterproof cloth (638). *British India*: Chemists' sundries, perfumery, soaps, patent medicines (630); paint (zinc, lead and various, ground and mixed), weldless steel (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *Bulgaria*: Drugs (B.X. 3586). *Canada*: Cocoa butter (631). *New Zealand*: Water meters, concrete mixing machines (633); steelwork (B.X. 3579). *Norway*: Leather (645). *South Africa*: Steel (A.X. 4815). *Spain*: Metal scrap (iron, steel, copper, gunmetal, brass, copper wire and heavy copper) (647).

Safeguarding of Key Industries

The Board of Trade give notice that the Treasury, by order dated June 23, have exempted under the provisions of section 10 (5) of the Finance Act, 1926, for the period from June 27, 1927, to March 6, 1928, the following articles from the duty imposed by section 1 of the Safeguarding of Industries Act, 1921, as amended by the Finance Act, 1926: ammonium perchlorate, dial (acid diallyl barbituric), Elbon (cinnamoyl para oxyphenyl urea), hydroquinone, integrators (planimeter type), R lead acetate, lipoidin, phytin, planimeters, potassium guaiacol sulphonate (thiocol), urea (carbamide).

British Standard Specifications

The British Engineering Standards Association has issued British Standard Specification No. 281—1927 for blanc fixe, No. 282—1927 for lead chromes (primrose, lemon, golden or middle, and orange), No. 283—1927 for Prussian blue, No. 284—1927 for carbon black, No. 285—

1927 for bone black, No. 286—1927 for vegetable black, No. 287—1927 for lamp black, and No. 288—1927 for mineral black. They contain clauses regulating the composition, together with standard reception tests, for the purchase of these materials, and appendices giving methods of carrying out the tests. These specifications have been prepared at the request of the paint manufacturers by a committee representative of both the buying and manufacturing interests, and as in the case of all British Standard Specifications, they will be reviewed as experience of their working or progress in the industry renders it necessary, and revised issues will be published from time to time. Copies of these eight new specifications (Nos. 281/288) can be obtained from the B.E.S.A., Publications Department, 28, Victoria Street, London, S.W.1, price 2s. 2d. each, post free.

News from Advertisements

1. The Department of Scientific and Industrial Research announces various vacancies for research chemists (p. vi).

2. A qualified chemist is wanted immediately for a mine on the Eastern Mediterranean coast (p. vi).

3. The Egyptian University, Cairo, requires a glass blower (p. vi).

4. The Air Ministry announces a vacancy for a test assistant in the Metallurgical Department of the Royal Aircraft Establishment (p. vi).

5. A routine worker is required in the laboratory of a large dairy company (p. vi).

6. The Manchester Municipal College of Technology announces particulars of various courses (p. vi).

7. The Royal Technical College, Glasgow, announces particulars of the forthcoming session (p. vi).

8. An expert in micro-chemical methods and photo-micrography seeks appointment (p. vi).

9. Chemist experienced in the manufacture of Bakelite products seeks position (p. vi).

10. A laboratory, together with quantities of apparatus and chemicals, for disposal (p. vi).

11. A Pensky-Marten's flash-point apparatus is wanted (p. vi).

12. There are 92 firms using the Buyers' Guide in this issue of CHEMISTRY AND INDUSTRY.

The Applications of Science

A SCIENCE grows, and can only grow, as other sciences and arts advance. Had the ancient Greeks, or the ancient Romans, known ten times as much chemistry as they did, the difference in their health, happiness and prosperity would have been quite trifling. A far greater knowledge of chemistry would have been necessary to make an appreciable difference to the Greek or Roman civilisation, and this additional knowledge could hardly have been obtained until engineering, physics and other subjects had themselves become of considerable importance. It is difficult to imagine real chemistry before the invention of the steam engine, of gas, of electricity, and of printing. Chemistry without cheap and reliable glass, the modern balance, the Buusen burner and the electric spark would only have been a complicated alchemy. It is probably because the applications of science would have done so little to benefit the ancient civilisation that these were so profoundly despised for so many centuries. Had these applications been many and obvious it is hard to believe that the greatest men of genius in the past would have rejected them as unworthy of consideration. That they did so consider them is undoubted; a distinguished writer who was a contemporary of Julius Cæsar had the temerity to allude to the discovery of the arch, and the use of metals, as benefits arising from the increase of knowledge. Seneca violently objected and pointed out that the aim of philosophy was to teach mankind to be independent of arched roofs and other material contrivances, that the invention of transparent windows, central heating for houses, and shorthand was drudgery only fitted for slaves, and that the only object of philosophy was to teach men to form their souls. The invention of the potter's wheel moved him to indignation. Plato, Aristotle, and Socrates had similar views; knowledge was to be sought for the good of the mind and for no material benefit to mankind; this doctrine long persisted in academic circles, but is

possibly now extinct. There must be very few people now in this country who dislike a new accession of scientific knowledge because it will probably be useful. Plato thought that the study of the theory of numbers raises the mind from the material universe to the contemplation of pure truth. Compare this with the following quotation from Helmholtz, referring to Lord Kelvin:—"He has striven with great consistency to purify the mathematical theory from hypothetical assumptions, which were not a pure expression of the facts. In this way he has done very much to destroy the old unnatural separation between experimental and mathematical physics, and to reduce the latter to a precise and pure expression of the laws of the phenomena." Last Sunday morning we motored to Gorbamby, near St. Albans, where Lord Bacon lived, and we thought of his prediction that, as more and more discoveries are made in physics, there will be more and more branches of mixed mathematics. Thomson and Tait, in their Treatise on Natural Philosophy, made mathematics the accurate servant for expressing the relation of facts, and to some extent they freed physics from the undue domination of formal mathematics. Socrates advocated the study of astronomy as a species of mental contemplation, but he would have scorned the prediction of the eclipse or the preparation of tables of the tides. Bacon advocated an astronomy which would set forth the nature, the motion, and the influences of the heavenly bodies, as they really are. The greatest men of genius among the ancients had a poor opinion of the invention of the alphabet and of the discovery of drugs to prolong the life of the ailing and suffering. Yet such men were skilled in geometry, and could prove that the square root of 2 could not be expressed as a vulgar fraction. In the year 1902 Sir William Ramsay wrote "When we consider the beginnings made by Gilbert, by Franklin, by Volta, and by Faraday, and contrast them with the outcome of these discoveries, the electric telegraph and the dynamo machine, we cannot avoid the inference that

the future has in store even greater developments than these. . . . Every encouragement should be given to the investigator, for it is to him that all our advances in physical and material well-being are ultimately due." The first man to make the world know that science could and should be used to make advances in our physical and material well-being was Bacon. He was the first and most powerful advocate of applied science, the man who directed science from the maze of Plato and Aristotle, to the path of Kelvin and Ramsay, the man who steered it from the mysteries of alchemy to the plain truths of applied chemistry. There is a great debt of gratitude owing to Lord Bacon; he was the spiritual founder of the Society of Chemical Industry.

The Annual Meeting

The Society of Chemical Industry has held many important annual meetings: they have had very different characteristics, but they have during recent years had one common feature in that they have been held in University cities. One of our greatest and oldest University cities has hitherto lacked the presence of our Society, but perhaps in the fullness of time this will be remedied. Welcomed as we are here by the University of Edinburgh and honoured by the presence of representatives of the other Scottish universities, we cannot help feeling how much we owe to academic men and academic institutions. The meeting in Edinburgh is well attended and successful, and the proceedings at the opening ceremony were unusually pleasant. The speeches were few and good: they gave the impression that the speakers had thought about their speeches. Mr. Evans was brief in explaining his financial summary and graceful in acknowledging his vote of thanks and the vellum book adorned with the autographs of his past and present colleagues on the Council. The President's address, which is published in full in this issue, is an admirable account of the part taken by chemistry in those developments of medicine which are concerned in the prevention and the cure of disease. The problem is not so simple as merely to discover a drug which will kill the disease organisms before it kills the patient. The experiments of Mithridates satisfied the world that a carefully selected dosage of poisons conveys a considerable degree of immunity. All the text-books state how Styrian peasants acquire the arsenic habit and how little injury is caused by it; the unanimous nature of these statements makes us suspect their truth, but that immunity can be obtained in some cases by such methods is an undoubted fact. Mr. Carr goes a long way towards explaining how the process operates. The chemistry of the body is extremely complicated, and has a very considerable system of automatic control; this is, by the way, not only true of the chemistry, but also of the physiology and anatomy of the body. It has an ordained future, and it offers considerable resistance to outside interference. Colonel Pollitt is only an extreme instance of this; we all possess it to an extent which only familiarity prevents us from considering as marvellous. Cut off the lizard's tail, it grows a new one; introduce into the human body bacteria in excess of the due immigration quota, and the body at once endeavours

to get rid of them; introduce drugs or other chemical compounds which are not part of the original scheme of work, and the same thing happens. The body resists the foreign elements, and if unsuccessful in its effort it does its best to neutralise their injurious activities. Mr. Carr gives us a number of illustrations of how this may be done. In some cases there is introduced a supply of external drugs which will kill the invading organisms or render them harmless; in other cases drugs are introduced which encourage the body to prepare its own destructive agency—its poison gas, as it were—to kill or incapacitate the hostile forces. The effect of this stimulus may persist after the invading force is subdued, or it may terminate before such a decision is reached. The Presidential address this year explains clearly and simply many of the steps in the process. His account of quinine, salvarsan, insulin, thyroxine, and the chemotherapeutical dyestuffs shows a part of the mechanism which is concerned. His account of the research which has led to our present degree of knowledge shows how, during the last five and twenty years, chemists and physiologists by working together have helped the physician to prolong human life and mitigate human suffering. The Society of Chemical Industry occupies a position which is quite unique; it is the only body in this country which includes in its wide ambit the application of chemistry to medicine, to the gas industry, to agriculture, to the manufacture of artificial silk and synthetic ammonia. It includes, of course, much more than this; it suffers—no, perhaps we should not say suffers, but rejoices—as the result of a diffidence such as, according to one of the speakers, is the predominant attribute of Mr. Carr and Mr. Evans. This diffidence, so far as the Society is concerned, is a species of pride such as is felt by the Scotsmen about their lochs and mountains, the kilt and the strathspey. They know how excellent they are, and if you are acquainted with these features of Scotland and do not think as they do, you are obviously not worth consideration. So in their estimation the man whose life will not be preserved by whiskey has a life that is not worth preserving. The Society is the focus in which rays from all the chemical reflectors meet; it has this other feature, which is typical of the focus: it does not make a great deal of noise. Perhaps that is why its annual meetings are so agreeable. We have our great men among us, men who have done work of outstanding and world-wide importance, but they give themselves no airs, thank Heaven, and chat with us ordinary mortals and offer us a cigar and introduce us to their wives and daughters until we hardly realise that these men will, by the next generation, be seen in their true proportions, standing head and shoulders above the rest. We read in our books in how kind a way Biot received Pasteur; we are too much surrounded by events to feel duly elated by having a cup of tea with Barger, or sharing a taxi-cab with Pollitt, or playing cards with Henderson and Carr. Nevertheless the way in which we members of the rank and file can mix with our undoubted leaders and learn from them at first hand their own views and the details of their own work makes these meetings very delightful. We judge that this meeting will be as interesting and pleasant as any we have attended.

NATURAL SOURCES OF ENERGY IN AUSTRALIA*

By PROF. JOHN READ, M.A., Ph.D.

General survey.—The chief natural sources of energy in Australia are coal, brown coal, and water power. Although two-fifths of the continent has a rainfall of less than 10 in. per annum, the possibilities of developing hydro-electric power in the eastern coastal zone, from Queensland to Tasmania, are very considerable. In the absence of natural petroleum, Queensland in particular offers attractive prospects for the production of power alcohol on a large scale. The occurrences of natural gas and kerosene shale are interesting but of minor importance.

Natural petroleum.—Although natural petroleum has not yet been discovered in Australia proper, it has been struck in small amounts in Papua, the part of New Guinea under Australian mandate. Oil from the Vailala field is remarkably clean and free from odour; it yields 36% of benzine and 46% of kerosene; and resembles Borneo petroleum in containing appreciable amounts of benzene and homologous aromatic hydrocarbons. It consists largely of paraffins, and pure specimens of $C_{23}H_{48}$, $C_{25}H_{52}$, and $C_{27}H_{56}$ have been isolated from the higher fractions (Read and Williams, J., 1919, 38, 319; Read and Andrews, J., 1920, 39, 289). From 1919 to 1921 the Anglo-Persian Oil Co. conducted an exploration of the territory of Papua for petroleum, aided by an allocation of £100,000 from the British and Commonwealth Governments; and more recently the Commonwealth Government has authorised advances up to £160,000 to persons and companies engaged in the search for commercial petroleum in Australia or Papua. Meanwhile, the annual Australian import of motor spirit and kerosene exceeds 40 million gallons. In Queensland signs of oil have been detected, and natural gas has been struck in enormous quantities, notably at Roma in the artesian basin 300 miles N.W. of Brisbane. The "wet" gas of Roma, encountered at a depth of 3,700 ft., yields 1·2 pints of liquid petrol per 1,000 cu. ft. when passed through suitable absorbers. Large supplies of "dry" gas occur in the Longreach area, about 400 miles N.W. of Roma, and as an indication of the former presence of petroleum two deposits of wax have been found in this district. It seems possible that low-pressure oil-beds may occur in Queensland, although it is unlikely that strong gushers will be struck.

Power alcohol.—Queensland is favourably situated for the production of power alcohol, since the cheapest sources—such as sugar-molasses, palm soap, and starchy plants like arrowroot and cassava—can be grown only in tropical or sub-tropical regions. At present about 10 million gallons of molasses are produced annually in the Australian sugar industry, and only about a quarter of this amount is utilised in making alcohol. The use of alcohol as a common motive power in Australia would necessitate an enormously increased production, which could not be met by the fullest utilisation of waste molasses. Consequently, the systematic cultivation of such crops as sorghum, cassava, and sweet potatoes,

for the production of power alcohol, may conceivably play an important part in the agricultural development of Australia. The whole question of the production and utilisation of power alcohol in Australia has been fully treated in Bulletin No. 6 (1918) of the Commonwealth Bureau of Science and Industry.

Coal.—Coal measures occur in eastern Queensland, Tasmania, and Western Australia, but the main worked deposits are in New South Wales, to the north and south of Sydney; altogether, Australia possesses about 2·2% of the estimated coal reserves of the world, or somewhat less than Great Britain. Coal-gas, coke, and ammonium sulphate are in great demand, but the population is too small for the maintenance of a coal-tar industry. At Mortlake, on Sydney Harbour, the Australian Gaslight Co. possesses one of the largest and most efficient gasworks in the world; it has a battery of 272 vertical retorts, and supplies gas over an area of 210 sq. miles. The Broken Hill Proprietary Co. has also erected a benzol plant at Newcastle. An electricity supply undertaking has been developed by the Department of Public Works of New South Wales at Port Kembla, on the southern coalfield 57 miles from Sydney. The present capacity is 20,000 kw., and the system will eventually interconnect with the Burrinjuck and Shoalhaven River hydro-electric schemes. The original object was to provide power for the construction of dams and other works, but it is hoped that the cheap power now available will foster industries and assist decentralisation.

Kerosene shale.—The kerosene shales of New South Wales are unique in their wide distribution and comparative abundance. The deposits occur on the margin of the coal area, in association with the permo-carboniferous upper coal measures, which lie below the Hawkesbury sandstone. The seams rarely exceed a mile in length or 5 ft. in thickness. The deposit at Hartley Vale, in the Blue Mountains, was known in 1824 or earlier, and the Scottish discoveries which brought oil-bearing shales into prominence were not made until many years later. On an average, the shales of New South Wales yield about 70% of volatile hydrocarbons and 14% of fixed carbon, the corresponding values for Scottish shales being 55% and 12·5%.

The deposits were worked for retorting and exporting from about 1865, but the industry languished with the exhaustion of the richer seams. From 1865 to 1901 the total output reached about a million tons, mainly from Hartley Vale and Joadja, valued at some £2,000,000. The price per ton fell from 49s. in 1885 to 15s. in 1901. Retorting grades now predominate over export grades, and shale oil is unable to compete with imported petroleum; so that the working of these deposits has been brought to a standstill. The inferior seams yield from 40 to 60 gallons of crude oil per ton. The magnificent deposit at Joadja, with 89% of volatile hydrocarbons and only 6·25% of fixed carbon, gave the phenomenal yield of 150 gallons of oil and 17,500 cu. ft. of gas per ton; the illuminating power of the gas was equal to that of 22 cwt. of sperm candles.

The available quantity of undeveloped seams is probably large, especially in the Capertree-Wolgan and Barigan areas (Carne); but in the absence of cheaper

* Summary of a lecture delivered on July 6 during the Annual Meeting of the Society at Edinburgh.

labour and interdependent industries the further exploitation of the kerosene shale deposits of New South Wales is problematical. Tasmanian shales are also known, averaging about 40 gallons of crude oil per ton; a specimen from the north-west of Queensland yielded only 20 gallons per ton.

Brown coal.—The most important deposits of brown coal in Victoria are situated in the Latrobe Valley area, including Morwell and Yallourn, about 80 miles south-east of Melbourne. The Port Albert area, which is easily accessible from the port of Welshpool, possibly offers 1000 million tons of "open cut" brown coal; this amount, however, is insignificant in comparison with the vast deposits of the Latrobe Valley (Herman). A third deposit at Altona, an outlying suburb of Melbourne, is deeper and expensive to mine. The first two deposits are State-owned, while the Altona field belongs to private corporations.

Victorian brown coal consists of a matrix of pollen grains, spore cases, and decomposed vegetable matter, with sporadic inclusions of lignite. It is brown or black in colour, and is easily reduced to a brown powder. As a rule, it contains more than 50% of moisture when freshly mined. The proximate analysis is very similar to that of Bittersfeld brown coal. Experiments conducted from 1918 onwards by the Department of Mines of Victoria have shown that the tar obtained by carbonising the brown coal at about 700° C. is much inferior, both in quality and quantity, to coal-tar; it contains a higher proportion of phenols than the latter material, and is also fairly rich in aromatic hydrocarbons. The yield of ammonium sulphate varied from 7 to 10 lb. per ton. When heated gradually to about 500° C., dried Morwell brown coal gave 27.5 gallons of oil and 1.75 lb. of ammonium sulphate per ton.

These investigations indicate the possibilities of carbonisation. Up to the present, however, little attention appears to have been paid to the much more important possibility of applying modern processes of hydrogenation to these vast deposits, with the aim of producing liquid fuels at economic rates. For the time being, the energy of the Victorian brown coal deposits is to be utilised solely by direct combustion of the raw material. Since 1918 the activities of the State Electricity Commission of Victoria have resulted in the erection of large State-owned power stations, associated with an efficient and extensive distribution service. An ultimate capacity of 150,000 kw. is proposed for the main power house at Yallourn, 6 miles from Morwell. The average overburden here is only 28 ft. of sand and clay, and the 150 million tons of brown coal which is estimated to exist in an area of 1 square mile to the south of the site should suffice to maintain such a power-house for 100 years. The coal is excavated from an open cut, 600 ft. wide, by means of electric shovels, which deliver through a travelling loader into trucks on an automatic rope haulage system. The first section of the power house, with a capacity of 50,000 kw., requires 4000 tons of coal and about 260,000 tons of water daily. The latter is obtained from the Latrobe River, and is used mostly for condensing the steam after its passage through the turbines, which are direct coupled to three-phase alternators generating at 11,000 volts pressure.

In recent years about two-thirds of the total output of German brown coal has been briquetted; some 20 million tons were treated in this way in 1922. A briquetting factory, with a maximum annual capacity of 100,000 tons, has been installed at Yallourn, where the steam-dried powdered coal is moulded, without any addition of binding material, under a pressure of 200 tons. Briquettes with 13.5% of moisture have a calorific value of 9000 B.Th.U. per lb. The loss incurred in operating the electricity supply in 1924—25 was £241,000, while the loss on briquettes in the following year was £40,000. It is estimated that by 1930 a profit should be manifest; and Yallourn will doubtlessly become an increasingly valuable asset to the State of Victoria. It may be taken as established, after lengthy and laborious investigations, that the low-grade brown coals of Gippsland can be utilised economically for the provision of electrical power, light, and heat; a rapid industrial development should follow the exploitation of these unique deposits, the harnessing of which must be included among the notable achievements of electrical practice.

Hydro-electric power.—It is proposed eventually to interconnect the Yallourn power system with the Sugarloaf-Rubicon and Kiewa River hydro-electric schemes; the initial capacity of the plant at the Sugarloaf reservoir has been fixed at 18,000 h.p. Of all the Australian States, however, Tasmania offers the best prospects for the development of hydro-electric power, a total amount of more than 500,000 h.p. having been definitely located and surveyed in the island. The Great Lake, with an area of 58 square miles, has a central situation 3350 ft. above sea level. A multiple-arch dam, 40 ft. high and 1180 ft. long, has been built across the southern end, and the Tasmanian Government Hydro-electric Department now disposes of 63,000 h.p. from the Great Lake scheme, through the power station at Waddamana, in addition to 12,000 h.p. from the Shannon River scheme. It is hoped to supply cheap hydro-electric power generally to townships and agricultural districts, and also to encourage the development of industrial concerns in Tasmania. At present the Electrolytic Zinc Co. of Australasia is the chief industrial consumer, 120 tons of electrolytic zinc being produced daily at the works at Risdon, near Hobart; hydro-electric power is also used by the same company in working the zinc-silver-lead deposits of the West Coast. The Australian Commonwealth Carbide Co., and Cadbury-Fry-Pascall, Ltd., also operate factories near Hobart by means of hydro-electric power. The rates prevailing in Hobart are 3d. to 5d. per unit for lighting, 1d. for domestic power, and ½d. to 2d. for motive power.

In New South Wales a power house has been erected at the Burrinjuck Dam, the primary purpose of which is to conserve water for the Murrumbidgee Irrigation Areas, some 200 miles further down the river. A first instalment of 5000 kw. is now available, with transmission to Canberra and through a closed ring system to Cootamundra and Wagga. Hydro-electric schemes are also contemplated at the Shoalhaven River in the south of the State and at the Clarence River in the north.

A good deal of water power is available in northern Queensland, and the Cairns Hydro-electric Power Investigation Board was constituted by Act of Parliament in 1922; irrigation schemes are also in progress in the Dawson Valley and Inkerman areas.

New Zealand also possesses very important resources of this kind, and altogether the available water power of Australasia has been estimated (Koehn and Kaplan) at about 30 million h.p., as compared with 100 million h.p. for the United States, 26 million h.p. for Canada, 59 million h.p. for Europe, and slightly less than 1 million h.p. for Great Britain.

Solar energy.—In conclusion, it may be pointed out that in time to come the sun-baked wastes of the "dead heart of Australia" will perhaps be made to pulsate with energy, as providing one of the most favourable regions in the world for trapping the energy of solar radiation by means of sun-engines. Ackermann's experiments with parabolic reflectors at Cairo, in 30° N. latitude, have demonstrated the possibility of securing 60 h.p. per acre of earth-surface in this way. The loss incurred through the angle of incidence of the radiation is here only 13%, and in Australia it would be sensibly less, seeing that the continent lies mainly to the north of latitude 30° S.

CANADIAN MINING AND METALLURGY

The International Nickel Co. will instal additional equipment at the Copper Cliff smelter, consisting of sintering furnaces etc. High grade copper ore has been discovered, in larger quantity, on the 2000 ft. level of the Frood mine, and instead of being a nickel proposition, it has developed into a question of copper production with nickel as a side-line, containing a high percentage of precious metals, principally platinum and palladium. The company is considering the question of the erection of a second electrolytic unit for the production of nickel at the Port Colborne, Ont., refinery.

The Consolidated Mining and Smelting Co. is extending its operations in British Columbia. The Sullivan mine, Kimberley, has a daily output of 4000 tons of ore. The company has purchased a controlling interest in the George Copper Mine, Bear river, Portland Canal district, B.C. It is anticipated that operations will soon be commenced at the Sunloch copper mine, Jordan river, near Victoria, and Coast copper mine, Quatsino, both situated on Vancouver Island. It is probable that a smelter will be constructed on the coast to treat these ores, and possibly also those from Britannia and other mines on the mainland.

The Flin Flon mine, situated in Northern Manitoba, north of The Pas, has passed from the prospecting stage, and the erection of a 3000-ton smelter is under the consideration of the Whitney syndicate (U.S.A.). The developed ore body above the 900 ft. level contains 20,000,000 tons of metalliferous ore of a complex character, carrying copper, zinc, gold and silver to the average value of \$13.40 per ton. It is estimated the metals can all be recovered for less than \$9.50, thus leaving a good margin for profit. Further exploration, below the 900 ft. level, may probably yield equally good ore.

COLOUR USERS' ASSOCIATION.

At the eighth annual meeting, held on June 28, the chairman, Mr. H. Sutcliffe Smith, in the course of his address, said that the Dyestuffs Advisory Licensing Committee had continued to carry out its duties. During the year 5800 applications for licences had been dealt with. The licences granted during 1926 showed a very large increase over the two previous years, the biggest increase being recorded in the imports from Germany. There was a marked increase in the quantity and value of the licences granted during 1926 as compared with the two previous years, but it must be remembered that the country's needs for foreign colour during the previous years were to a large extent met from Reparations, the imports of which ceased at the end of 1924. It was, however, a matter for serious consideration by the British makers that it was yet necessary to license the import of nearly 1,900 tons of colour, value £944,000.

The statement had often been made that 80% of the colour used in this country is of British manufacture, whereas pre-war the position was reversed, and 80% of the colour used in this country was of foreign manufacture. That was a great achievement of the British makers. It was, however, a matter for serious reflection that, whereas now only 20% of the colour used in this country represented by the foreign imports aggregates £944,000, pre-war 80% of the consumption was valued at only £1,800,000.

Although the world's capacity for the production of dyewares is now nearly twice that of pre-war, the prices of dyewares throughout the world had not yet fallen to the general level of wholesale prices. On the other hand, it has to be borne in mind that as the class of colour now generally used is of a much better type than formerly, and there has been a marked increase in the use of vat and other high-class dyes on account of their fastness to washing and light, and the demand on the part of the consumers for superior dyed fabrics, the cost of dyewares has gone up very considerably. It was estimated that, whereas in 1913 the colour bill of this country was approximately £2,000,000, to-day, with a reduced output, it must be not less than £5,000,000. This increase must not be taken as an increase in the cost of the same types of dyewares, but as very largely due to the use of these higher grade dyes already mentioned. There is no doubt that the textile trade to-day was giving a much higher standard in dyeing and finishing.

The activities of the Joint Technical Committee, which consists of technologists representing both dye-makers and users, have been mainly confined to the revision of the "non-contentious" list, that is to say, the list of colours for which there are no adequate substitutes made in this country. It is nearly five years since the list was compiled, and, whilst modifications have been continuously effected, it has long been felt that a complete revision was desirable in order to make it more representative of the current situation. It was eventually decided that the position could be met by dividing the list into two parts, viz. :—

List A.—Products which are in substantial consumption, and for which no adequate substitutes are available.

List B.—Products for which no exact equivalent of British manufacture is available, but which are

- (1) Capable of substitution, for purposes of major importance, by existing British products; and/or
- (2) Used in such small quantities that their addition to the "A" list is considered undesirable.

Applications for licences to import products included in "A" list would be granted immediately and without question, whilst those in the "B" list may be queried by the Technical Advisers to the Dyestuffs Advisory Licensing Committee where substantial evidence has been submitted by a British maker of his ability to supply a satisfactory substitute. The simplification of these lists will be of the greatest assistance to the Dyestuffs Advisory Licensing Committee.

Part I of the Safeguarding of Industries Act of 1921, which imposed import duties on a scheduled list of synthetic, organic and fine chemicals, expired in August, 1926. Before this date, however, the President of the Board of Trade set up a private Committee to advise him as to what action should be taken when this portion of the Act expired. The recommendations made by the Committee were included in the Finance Act of 1926, the period of operation of Part I of the Act being extended for a further 10 years, and subsequently the Board of Trade issued a supplementary list of over 500 synthetic, organic and fine chemicals for inclusion as dutiable articles. The Association took advantage of the new provision for the exclusion of dutiable articles included in the list, but not manufactured in the country, by putting forward a requisition that oxalic acid should be exempted from duty under the Act, and in due course the removal of the duty on this article for one year was notified by the Board of Trade.

It was opportune to give an expression of the general views of users on the formation of Imperial Chemical Industries, Ltd. The experience of modern, large-scale industry, especially in America and Germany, had shown the value of large combinations in the realisation of the best economic results, and if this country was to maintain its commercial position it could not afford to ignore this new trend. The merging of the great chemical manufacturers of Germany made it imperative that the British and Imperial chemical industry should form an equally united front, and this new formation should place the British industry in a position to deal with similar large groups in other countries on equal terms.

After discussing the advantages of big-scale production, Mr. Sutcliffe Smith said there was a fear that by the elimination of selling competition the users might be exploited not only nationally, but internationally. So long as industry was controlled by men of ability and integrity, as we had in the large-scale industries in this country to-day, he thought there was no ground to fear monopolistic dangers.

Steady progress was being made by the British dye-making industry. In 1913 Great Britain produced only about 5000 tons of aniline dyes, equivalent to 3% of the world's production, whereas in 1925 (the latest published figures) the production amounted to nearly 15,000 tons, or approximately 10% of the world's production. With the exception of the United States, no other country had made such remarkable progress in the production of dyestuffs. The estimated capacity of

the British makers was upwards of twice the current output. The progress had been phenomenal, and it was gratifying to those who had confidence throughout those strenuous years that the British dyemaking industry would eventually take its place as an important factor in the world's production of dyewares.

One of the secrets of success of the great German dye producers before the war was attributable to the excellent technical service which they rendered to their users. Not only was this service beneficial to the recipients, but it assisted in the development of the industry by bringing the manufacturers regularly into contact with the difficulties and problems of the users and their requirements. The British makers were evidently fully alive to this aspect, and with their experimental laboratories, manned with highly trained technical staffs, they were now able to give British users a service and assistance which cannot be surpassed.

In addition to introducing new colours to the market and producing equivalents for many colours which were formerly imported, considerable progress had been made in the production of colours for other industries. Mention might be made of the new group of level colours introduced by the British Dyestuffs Corporation, Ltd., as a solution of the long outstanding problem of the variability of the dyeing properties of viscose, and the new series of Coricol colours which will be of the greatest assistance to the leather industry of this country. The application of physics to dyeing problems has not been lost sight of in the production of wetting out agents and insoluble colours in a dispersed form.

He was glad to be able to record these achievements on the part of British makers, because he felt that in far too many quarters British progress was underrated. In this highly technical industry it had been amply demonstrated what British chemists and chemical engineers have been able to do in a short space of time, and it had shown that in technical skill they were equal to any demands that may be made upon them. Whilst there were many products which it is yet necessary to import, it could not be expected that it should be otherwise, as it was not possible for British makers to achieve in ten years what it took the great German industry fifty years to accomplish.

The undoubted progress of the German dyemaking industry was largely due to the fact that it had a large export trade, its output for the overseas market being many multiples of its internal consumption. Production on an adequate and economic scale in this country will only be achieved when British exports are on a similar scale to those of Germany. The following figures show the exports of dyes and dyestuffs obtained from coal tar as furnished by the Board of Trade:—

Year	Weight Cwts.	Value £
1913	48,673	177,246
1924	104,396	923,933
1925	104,161	847,639
1926	75,727	614,112

These figures were encouraging, showing that the exports in weight had decidedly increased over pre-war, but it was unsatisfactory to note that 1926 shows a marked decrease on 1925.

In making another plea for closer co-operation and liaison between the universities and the dyestuffs industry, he felt confident that the leaders of the chemical industry would not lose sight of the importance of this aspect in the development and progress of the chemical industry, and the dyemaking industry in particular. There was need for the establishment of a scheme whereby the expert knowledge and power for research embodied in our university organisations may be utilised to the fullest extent in the practical laboratories of manufacturers. A large amount of research work was being done in these works and laboratories, and there was a great amount of unofficial co-operation between all sections of the industry. But there was considerable scope for close liaison between the academic and the practical institutions. We had only to consider the great progress made in the German chemical industry by arrangements of this nature to realise the benefits that can be derived from them. More emphasis should be laid on the possibilities and advantages to be gained by an enlargement of research service in an almost undeveloped direction, by an extension of co-operative research work on lines which, while modified by the particular circumstances of the case, would follow very much on those adopted for co-operation on the wider scale. Such mutual arrangements between firms and firms, and, more important, between firms and universities and other research organisations, would lead to a more economical use of the service, and prevent the overlapping which is very obviously the chief defect in the present system. If such a suggestion were to be followed up in practice, there was little doubt that there would accompany it that still further development of the application of research which is necessary for the future success of our chemical industry.

Considerable attention had been devoted in the Press recently to the reopening of negotiations between the chemical interests of Great Britain and the Interessens Gemeinschaft of Germany. It would be remembered that in 1924 the Association took an active part in the opposition to the agreement proposed then between the British Dyestuffs Corporation, Ltd., and the Interessens Gemeinschaft. As users, we affirmed two main principles:—(a) The colour users must be assured of free access to the best quality and range of dyestuffs produced anywhere, and (b) users must be on as favourable terms as regards prices as any of their world competitors, and these prices should not be on such a basis as to retard the sale of their productions in overseas markets.

The full terms of that agreement were never disclosed to the public, but it is evident there was not entire satisfaction on these two principles, as the Government refused to sanction the arrangement.

Mr. Sutcliffe Smith said he was of the opinion, and he believed he voiced the sentiments of the principal users of this country, that an agreement on sound lines, safeguarding our two main principles, and whereby there would be a proper interchange of technical and manufacturing knowledge, would not be disadvantageous to British users and the world generally; but there must be no risk of an arrangement in which the British manufacturers would not be on an equal footing with the Interessens Gemeinschaft, and by which the British industry would not be progressive.

Just as fusion of the large units in this country should lead to beneficial results in an economic sense, so it must be apparent that international co-operation should not be detrimental. In any new international arrangement the two principles already stated would require to be held sacred. The effects of consolidation should be reflected in quickened research, leading to rapid developments in the production of new types of dyestuffs and chemicals at still lower prices, thus assisting the textile and other colour-using trades to regain their peak volume of business. In the event of an international amalgamation the British user would expect the suspension of the Dyestuffs (Import) Regulation Act, and the supersession of the present cumbrous licensing system by free access to the world for his dyestuffs. The time was ripe for such an arrangement, now that the British industry with its united front was in a position to meet the German manufacturers on an equal footing.

The sacrifices made by the users during the past six years under the restrictions imposed by the Dyestuffs (Import) Regulation Act in paying prices considerably above the world's lowest rates must not have been in vain. Users were as determined as ever that a virile dyemaking industry should be maintained in this country capable of supplying its needs at all times. It was now recognised that the manufacture of dyes is of first importance, not only as a key industry in the production of textiles—the largest export of wholly or partly-manufactured goods, representing 40% of the total—but also by virtue of its potentialities as a research medium. The basis of such an industry is continuous research for the discovery of new products, the improvement in manufacturing processes, and the utilisation of by-products.

This industry should form a training ground for the development of chemists and technicians, and their employment for other industries, a factor which was fully recognised by the Germans in the development of their dye industry. There is no doubt that to-day British technologists are competent to deal with any of the intricate problems which face modern industry. The heavy chemical industry of this country is proof of the fact that Great Britain has not been lacking in the production of scientific inventors in the realm of chemistry, and the number is as large as in any other country.

Considerable attention was devoted by the recent International Economic Conference in Geneva to the development of the chemical industries. There were two distinct counsels. It was urged in the memoranda submitted by the German Section that the future success lay in confining the production of a chemical to those countries in which the conditions of manufacture are most favourable. The British point of view differed. It was urged in the British memorandum that the protection of the chemical industry "goes somewhat beyond that of self-sufficiency, profit or employment," and that it was "to render secure an outlet for the abilities and desires of educated workers and craftsmen and to afford the workers an opportunity for the exercise of the greatest amount of skill." The British point of view was particularly applicable to the dyestuffs industry, because, apart from its being a training ground for chemists, on it is dependent the commercial development of the infinitely greater textile and other industries.

As a result of negotiations opened by the Association, the Dyestuffs Advisory Licensing Committee had reduced the $2\frac{1}{2}$ times factor to 2 times, when considering applications for licences to import dyestuffs on price grounds. This seemed a very striking indication of the progress the British dyemaking industry was making in that they are now able to meet the lower factor. This should place them in a much stronger competitive position to obtain new business immediately, and as progressive reductions take place in the factor during the remaining period of the Dyestuffs (Import) Regulation Act, the dyemaking industry should be in a position, at the expiration of that period, to meet world competition without artificial assistance.

Considering the price of British dyestuffs, it was observed that the average import price per pound in 1926 showed an increase over 1925. As there were price reductions during 1926, it would appear that the increase in the imported price was mainly due to the use of better types, which was reflected in an improvement in the dyeing and finishing of textile goods.

The general level of prices, however, not only in this country but on the Continent and in America, was considerably higher than it should be, and it was hoped that the co-ordination and development of the chemical resources of this country arising out of the formation of Imperial Chemical Industries would result in an early reduction.

He agreed with the statement in the monograph on the chemical industry submitted to the Economic Conference of the League of Nations that sufficient emphasis was not always laid on the auxiliary products used in the textile industry. The total quantity or value of dyestuffs used in the production of textiles appeared to be small as compared with the heavy chemical products used in that industry. There was no doubt that the price of chemicals was a very important item in the cost of production in the colour-using industries, particularly the textile trade. Not only did these costs affect chemicals directly used, but they had a material bearing indirectly in that they are a component part of the cost of dyestuffs. It was satisfactory to find that in many instances the prices of chemicals, as related to the prices ruling in 1914, compare favourably and are approximately on a level with the Wholesale Prices Commodity Index figure. It was to be regretted, however, that there were yet far too many chemicals used in large quantities, the prices of which are much too high. Attention had been directed to this, not only by users, but also by colour makers themselves, owing to the adverse effect it had upon the cost of their intermediates. It was to be hoped, therefore, that the economies foreshadowed by Sir Alfred Mond in connection with the new merger company will reflect themselves in a speedy revision of those prices which users consider are yet too high.

In conclusion, attention was directed to the important changes in industry which were being made almost daily. Many had happened in the past; many more will develop in the future. If we were to maintain our position in the forefront of industry, all that combined effort, vigilance, and wise policy can bring to us will be needed.

MINERALOGICAL SOCIETY

A meeting of the Mineralogical Society was held on June 14, Prof. W. W. Watts, F.R.S., the President, in the chair. The following papers were read:—

"The atomic volume relations in certain isomorphous series," by A. F. Hallimond. The paper was based on accurate data made available by the researches of Dr. Tutton and other workers. For isomorphous salts of the eutropic elements K, Rb, Cs, the differences Cs-K and Rb-K stand in constant ratio, and the same ratio holds good for the free metals, though these are considerably larger than in the combined state; the constancy does not extend to the salts of NH_4 or Tl. A modified additive relation was indicated, the volumes of the metals when free and when combined being in the same ratio as the differences for the free metals and for the respective isomorphous series. In the same way, volumes can be calculated for combined Na and Li from those from the free metals. Salts of Cl, Br, I exhibit a similar constancy in the ratio of their differences, and this would appear to be a distinctive character of each "eutropic" group of elements. Volumes are calculated for combined Cl, Br, I. These and other values for the acid radicles in the above series are in very close agreement with existing knowledge of the size of the atoms, a fact which affords strong confirmation of the validity of the method now proposed for computing the volume of the elements in the combined state.

"The Petrology of the Bodmin Moor granite (eastern part), Cornwall," was described by Dr. P. K. Ghosh, and "The distribution of purple zircon in British sedimentary rocks" was described by Prof. P. G. H. Boswell.

" β -Quartz twins from Cornwall," by Dr. J. Drugman. β -quartz seems to be sufficiently differentiated from α - or low-temperature quartz for the two to be treated quite apart from each other. This is specially the case with the twin-laws observed in these.

"The separation of manganese in rock analysis," by E. V. Holt and Dr. H. F. Harwood. In carrying out the exact analysis of rocks, the whole of the manganese they contain can be completely precipitated with the alumina and ferric oxide by employing the following procedure:—The solution, after removal of silica, is diluted to 400 c.c., heated to boiling after the addition of ammonium chloride, and ammonia added to alkalinity. Bromine water is then run in slowly from a tap funnel, whose stem is drawn out to a fine jet, small additional quantities of ammonia being simultaneously added to keep the solution alkaline. When the addition of the bromine is complete, the liquid is boiled for one minute, and then filtered. The precipitate is re-dissolved and the precipitation repeated; in the combined filtrates, lime and magnesia are determined by the usual methods.

"Corundum twins from Transvaal," by Dr. L. J. Spencer. Large twinned crystals of corundum, up to 6 inches across, but only about an eighth of an inch thick, are abundant in plumasite rock near Bandler Kop, northern Transvaal. The twin-plane is a face of the primary rhombohedron, and the twinned crystals have a form resembling arrow-heads.

CORRESPONDENCE

A QUESTION OF PROPAGANDA

SIR,—In reading your Editorial in the current issue, I could not help being struck by one sentence. It started admirably, but the concluding sentence simply nullified the whole effect.

"We ourselves make a point of invariably using the term pharmacy instead of chemist's shop."

So far so good. Now for the bathos, "except when we ask a maid or a child or the gardener to buy something for us."

I venture to express my humble opinion that this is just where you are losing a golden opportunity to do a little propaganda. If the maid, child or gardener is more than usually intelligent, you can also add that the letters M.P.S. over the shop door mean Member of the Pharmaceutical Society, so that the gentleman concerned probably much prefers to be called a pharmacist.

A small point perhaps, but if all our 5000 members adopted this attitude consistently year after year public opinion would certainly be influenced favourably.—Yours, etc.

R. FARADAY INNES

PERSONAL AND OTHER ITEMS

Mr. George Gray, Prof. G. T. Morgan, F.R.S., Mr. L. Guy Radcliffe, and Mr. Harold Talbot have been elected to the Council of the Society of Chemical Industry.

During the Oxford Encœnia last week the honorary degree of D.Sc. was conferred upon Sir Robert Hadfield, F.R.S., who was welcomed by the Vice-Chancellor as *vir strenuissime, in metallurgia spectatissime, callide novas ferri coquendi artes reperire. Cyclopus officinis ignotas*. Prof. R. Wüstätter, who also received the honorary degree of D.Sc., was admitted by the Vice-Chancellor as *vir doctissime, in Chemia Organica spectatissime, qui indagavisti unde florum nascantur colores, quibus fermentis, vita animalium et plantarum alatur et sustentetur*.

On Saturday last at the Degree Congregation of the University of Birmingham, the honorary degree of Doctor of Laws was conferred upon Prof. Arthur Lapworth, F.R.S., Chemistry Department, University of Manchester. The Principal (Dr. Grant Robertson) pointed out that the Professor was a son of Prof. Charles Lapworth, of the Geological Department of Mason College, Birmingham, and was a former student there. Prof. Lapworth had placed himself in the front rank of investigators by his work on synthetic chemistry, and had made a place for himself amongst the British chemists of his generation by his insight in developing a broad analysis of the meaning of chemical reactions and by his stimulating contributions to the dynamics of chemical phenomena.

Emeritus Prof. H. Louis, M.A., D.Sc., has been elected to succeed Dr. T. S. Haldane as President of the Institution of Mining Engineers.

Dr. H. Levinstein has been elected president of the Society of Dyers and Colorists.

The University of Maryland has conferred the honorary degree of D.Sc. on Sir John Russell, F.R.S., director of the Rothamsted Experimental Station.

Mr. Christopher Barber has been appointed general manager of Silica Gel, Ltd.

Dr. E. C. B. Wilbraham has taken up an appointment with the Pyrene Co., Ltd.

Mr. A. C. B. Mathews has accepted an appointment with Messrs. Naylor Bros., Ltd.

Mr. B. F. Conigrave has joined the board of the British Cyanides Company.

Dr. L. Harris, who was awarded the Meldola Prize by the Institute of Chemistry two years ago, has been appointed director of the research institute which is to be erected in Cambridge under the control of the Medical Research Board.

The degree of D.Sc. in chemistry has been awarded by the Birmingham University to J. A. V. Butler, for numerous papers on "Studies in heterogeneous equilibria," and to H. A. Scarborough, for papers on "Saponification and properties of mixed solvents."

The London University has conferred the following doctorates:—D.Sc. in chemistry on F. H. McDowall, for a thesis entitled "Constituents of *Myoporum laetum* Forst (The 'Ngaio')"; I. R. McHaffie, for a thesis entitled "The effect of the presence of an indifferent gas on the concentration and activity of a vapour in equilibrium with a condensed phase or system of condensed phases"; S. O. Rawling, for a thesis entitled "The sensitivity of photographic emulsions"; and F. Tattersfield, for a thesis on "The relationship between the chemical constitution of organic compounds and their toxicity to insects."

Research in Mining at Sheffield

A new mining department is to be erected at the University of Sheffield at a cost of £21,200. The new department will provide facilities both for education and for the investigation of important mining problems.

New Acts in Force

On July 1, the Public Health (Smoke Abatement) Act, 1926, which extends and revises the provisions of the Public Health Act, 1875, and the Public Health (London) Act, 1891, came into force, and on the same day the regulations prohibiting the use of preservatives in food were made applicable to bacon, ham, egg yolk and articles containing preservatives introduced by the use of preserved margarine.

British Sugar Beet Society

At the meeting of the British Sugar Beet Society, Ltd., held on June 14, Mr. G. H. Roberts, who presided, submitted a resolution winding up the society. The society, he said, had accomplished the purpose for which it was founded, and since its activities affecting beet growers had been transferred to the National Farmers' Union, while the various factory companies were forming themselves into a manufacturers' association, there was no longer any need for its continuance. Sir James Martin seconded the resolution, and said that the subscribers and guarantors were agreed on the necessity of this step, and as the Executive Committee had reported that the society should be wound up, the resolution should be agreed to. In making an amendment to the resolution Colonel E. Royds stated

that the society had a balance of £1,000, and he believed the guarantors would be willing that that should be devoted to the future work of the society. He believed it had a big future. Other bodies which were to take over some of its functions were not as yet in existence, and there was much the society could do in assisting and encouraging the provision of new factories, obtaining Government support, preventing overlapping, and preventing disputes between growers and factories. Colonel Malcolmson, who seconded the amendment, said that the feeling of unrest overseas, with regard to the development of sugar beet, made the continued existence of the society desirable. No other body could carry on so effectively the non-political propaganda of the society.

After further discussion the chairman said he had been for years a prominent worker in the society, and it was only after very careful consideration that he had come to the conclusion that the society's purpose had been fulfilled. There was no object served by keeping a society in existence if they were not able to finance it. The four members present who opposed the winding-up of the society were asked to review the situation and then to meet the Executive Committee at a further meeting of the society. This was agreed to.

PARLIAMENTARY NEWS

Safeguarding of Industries (gas mantles)

Sir Philip Cunliffe-Lister informed Mr. Harris that the imports of gas mantles in the first four months of 1925, 1926 and 1927, respectively, were 67,656 gross, 14,958 gross, and 11,203 gross. The average price realised by members of the trade association on the sale by them of all their mantles during the year ended on March 31 last showed an increase of 1s. a gross on the average price realised by them during the preceding year. These sales were estimated to cover 85% of all the mantles sold in this country. Against this there had been increases in the cost of certain materials. The retail prices of the classes of mantles most commonly used had, so far as could be ascertained, remained substantially unchanged. —June 28.

Production of Crude Petroleum

In reply to Mr. John, Sir P. Cunliffe-Lister said that the world production of crude petroleum was estimated to have been about 47 million tons in 1910, 62 million tons in 1915, 98 million tons in 1920, and 150 million tons in 1926. — June 28.

Beet Sugar Subsidy

In a written reply Mr. Guinness informed Mr. Thurtle that the expenditure during the financial year ended March 31, 1927, in respect of the subsidy on home-grown beet sugar and molasses was £3,225,858. Of this amount, approximately £1,004,300 was returned to the State in the form of Excise Duty. There had been no remission of Excise Duty since the passing of the British Sugar (Subsidy) Act, 1925. — June 29.

Sugar (Clearances)

In answer to Sir J. Power, Mr. McNeill stated that the quantities of sugar cleared during the two months of April and May, 1927, for home consumption were as follows:—Imported refined sugar, 2,029,000 cwt., British refined sugar, 2,744,000 cwt., sugar manufactured from home-grown beet, 295,000 cwt.—June 29.

COMPANY NEWS

MOND NICKEL CO., LTD.

The gross profits for the year to April, 1927, amounted to £528,730, compared with £574,371 for 1926, and the net profit, after providing £73,750 for interest on debentures (against £96,393) and meeting general charges of £60,267 (against £52,943), amounted to £394,712, a reduction of £30,323. It is proposed to maintain the dividend at 12½%, less tax, by a final payment of 1s. 6d. per share. After placing £15,000 to debenture stock reserve, and allowing £19,735 for directors' fees, the balance of £33,189 has been carried forward, compared with £48,212 brought in. The coal trade stoppage seriously interfered with refining operations, and the costs of production were increased in consequence.

CASSEL CYANIDE CO., LTD.

The directors have issued a circular to shareholders regarding the exchange of shares into Imperial Chemical Industries. For two existing Cassel shares of 5s. each there will be exchanged £1 ordinary share in Imperial Chemical Industries, Ltd., and, in addition, for each five existing Cassel shares of 5s. each there will be exchanged 1 deferred share of 10s. each in Imperial Chemical Industries. The offer is conditional upon its acceptance by the holders of not less than 75% of the shares.

WESTERN VISCOSE MILLS, LTD.

The first ordinary general meeting was held on July 1, Sir Drummond Drummond Fraser, K.B.E., chairman, presiding. The company was concentrating on quality and testimony had been forthcoming that the company's yarn was one of the best on the market. The yarn had had a ready sale from the first, and negotiations were pending with large buyers for home and overseas trade. Sir Max Muspratt, Bart., said that the manufacture of artificial silk was a combination of complicated chemical and engineering processes, with no small demand on human skill. Apart from the inevitable delays in completing equipment, due to the coal stoppage, most praiseworthy progress has been made, and the successful launching of large-scale manufacture reflected the greatest credit on the management. Great expense was saved by the careful study of each stage of the process in the experimental plant, the unavoidable losses of starting a new process thus being incurred in hundred-weights instead of in tons. The highest quality of viscose silk was being aimed at, and, with all the experience and training gained, was being steadily attained; it also dyed well.

BRITISH CELANESE, LTD.

An extraordinary general meeting was held on June 30, at which resolutions were confirmed for the removal of certain directors, namely, Mr. J. G. Raphael, Capt. the Rt. Hon. F. E. Guest, and Mr. L. Chandler. Dr. Dreyfus, who presided, referred to the financial position of the company, and said that it might be that no reorganisation would be necessary. He would recommend to the Board such a scheme as would deal with the position in such a way that it would not take too long. The potentialities of the business and its earning power were the main factors.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton. f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Sal ammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide cryst.—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.
 India-rubber Subst^tutes, White and Dark.—5½d.—6½d. per lb.

Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—9d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron."—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—6s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carboic.—Crystals,—8d.—9d. per lb. Crude 60's, 2s. 6d.—2s. 8d. per gal.
 Acid Cresylic, 90/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 3½d. per gal. Pale, 95%, 2s.—2s. 1½d. per gal. Dark, 1s. 9d.—1s. 10d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 11d.—1s. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluene.—90%, 1s. 8d.—1s. 10½d. per gal. Pure, 2s.—2s. 3½d. per gal.
 Xylol.—1s. 11d.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%.—10½d. per gal. Standard specification, 6½d.—9d. per gal. Middle Oil, 7½d.—8d. per gal. Heavy, 8½d.—8½d. per gal. Salty, 7d. per gal., loss 1½%.
 Naphtha.—Crude, 7½d.—8d. per gal., according to quality. Solvent 90/100, 1s. 5d.—1s. 6d. per gal. Solvent 95/100, 1s. 5d.—1s. 6d. per gal. Solvent 90/100, 11d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals,—£11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—77s. 6d.—85s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis. d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.
 Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorbenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 4½d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—5 cwt. lots. Cryst. 41s. per cwt. Powder 45s. per cwt. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 7½d.—1s. 10d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. pulv. 1s. 4d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 8d.—2s. 10d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £39 per ton, in 5-cwt. casks. Resublimed.—1s. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. per lb.
 Benzophenanthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—5 cwt. lots. Crystal 25s. per cwt. Powder 27s. per cwt., according to quantity, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 3d.—2s. 4d. per lb. Potassium.—1s. 10d.—1s. 11d. per lb. Sodium.—2s.—2s. 2d. per lb. All spot.
 Calcium Lactate.—1s. 3½d. per lb.
 Chloral Hydrate.—3s. 6d. per lb., duty paid.
 Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.
 Creosote Carbonate. 6s. per lb.
 Ethers: Prices for Winchester quarts; dozen Winchester quarts; carboys or drums; and 10 cwt. lots respectively; 730—1s. 2½d.; 1s. 2d.; 1s. 1½d.; 1s. 0½d.; 720 tech.—1s. 5½d.; 1s. 5d.; 1s. 4½d.; 1s. 3½d.; 720 pur. (Aether P.B. 1914)—2s. 4d.; 2s. 3½d.; 2s. 3d.; 2s. 2d.
 Formaldehyde.—£39 per ton. Ex wharf in barrels.
 Guaiacol Carbonate.—5s. per lb.
 Hexamine.—2s. 4d.—2s. 6d. per lb.
 Homatropine Hydrobromide.—30s. per oz.
 Hydrastine Hydrochlor.—English make offered, 120s. per oz.
 Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ½ lb., 9s. 6d. per doz.; ¼ lb., 6s. 6d. per doz. 10 vols.—2s. 3d.—2s. 11d., according to quality and package.
 Hydroquinone.—2s. 11d. per lb.
 Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.
 Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.
 Iron Perchloride.—4d. per lb., 22s. per cwt., according to quantity.
 Magnesium Carbonate.—Light Commercial £31 per ton net.
 Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.
 Menthol.—A.B.R. recryst., B.P., 18s. 6d. per lb. net. Synthetic detached crystals, 11s. 6d.—14s. 6d. per lb., according to quantity; Liquid (95%), 12s. per lb.
 Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.
 Methyl Salicylate.—1s. 6d.—1s. 8d. per lb.
 Methyl Sulphonate.—9s. 6d.—9s. 9d. per lb.
 Metol.—11s. per lb. British make.
 Paraformaldehyde.—1s. 9d. per lb. 100% pdr.
 Paraldehyde.—1s. 2d.—1s. 4d. per lb.
 Phenacetin.—2s. 9d.—3s. per lb.
 Phenazone.—4s. 3d.—4s. 6d. per lb.
 Phenolphthalein.—6s.—6s. 3d. per lb.
 Potass. Bitartrate.—99/100% (Cream of Tartar) 100s. per cwt., less 2½% for ton lots.
 Potass. Citrate.—1s. 11d.—2s. 2d. per lb.
 Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.
 Potass. Iodide.—16s. 8d. per lb. for 1 cwt. lots.
 Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.
 Potass. Permanganate.—6d. per lb. spot.
 Quinine Sulphate.—2s. per oz.; 1s. 8d.—1s. 9d. per oz. in 100 oz. tins.
 Resorcin.—3s. 9d.—4s. per lb. spot.
 Saccharin.—55s. per lb., and lower in quantity.
 Salol.—2s. 4d. per lb.
 Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.
 Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.
 Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—90s.—97s. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonal.—6s. 6d.—6s. 9d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s.—2s. 2d. per lb.

Thymol, Puriss.—10s. 3d.—11s. 6d. per lb., according to quantity. Natural.—15s. per lb.

PERFUMERY CHEMICALS

Acetophenone.—7s. 3d. per lb.

Aubepine (*ex Anethole*).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. **Amyl Butyrate.**—5s. 3d. per lb. **Amyl Salicylate.**—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. **Benzyl Alcohol** free from Chlorine.—2s. per lb. **Benzaldehyde** free from Chlorine.—2s. 6d. per lb. **Benzyl Benzoate.**—2s. 6d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 9d. per lb.

Ethyl Cinnamate.—7s. 6d. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. **Geraniol** (Palmarosa).—17s. 6d. per lb. **Geraniol.**—6s. 6d.—10s. per lb. **Heliotropine.**—4s. 9d. per lb. **Iso Eugenol.**—13s. 6d. per lb. **Linalol.**—(*ex Bois de Rose*) 15s. per lb.—(*ex Shui Oil*) 10s. 6d. per lb. **Linalyl Acetate.**—(*ex Bois de Rose*) 18s. per lb.—(*ex Shui Oil*) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. 6d. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—3s. 9d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—32s. 6d. per lb. **Safrol.**—1s. 6d. per lb. **Terpineol.**—1s. 6d. per lb. **Vanilin.**—17s.—18s. 6d. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. **Anise.**—3s. 1d. per lb. **Bergamot.**—28s. 6d. per lb. **Bourbon Geranium.**—14s. 6d. per lb.

Cumpher.—67s. 6d. per cwt. **Cananga, Java,** 26s. per lb. **Cassia, 80/85%.**—8s. 3d. per lb. **Cinnamon, Leaf.**—6d. per oz. **Citronella.**—Java 85/90%, 1s. 11d. per lb., Ceylon, Pure, 1s. 9d. per lb. **Clove, pure.**—6s. per lb.

Eucalyptus, 75/80%.—2s. 4d. per lb. **Lavender.**—Mont Blanc 38/40%, 21s. per lb. **Lemon.**—8s. per lb. **Lemon-grass.**—4s. 6d. per lb. **Orange, Sweet.**—10s. 6d. per lb. **Otto of Rose.**—Anatolian, 30s. per oz., Bulgarian, 70s. per oz. **Palma Rosa.**—10s. 6d. per lb. **Peppermint.**—Wayne County, 18s. per lb. **Japanese,** 8s. per lb. **Petitgrain.**—7s. 6d. per lb. **Sandalwood.**—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Aug. 27th. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on July 14th. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

Akt. Separator. Treating liquids. 16,348. June 20. (U.S., 22,626.)

British Thomson-Houston Co., Ltd. (General Electric Co.). Refrigerator evaporators. 16,628. June 22.

Chapman. Separation of substances of different specific gravity. 16,798. June 24.

Chem. Fabr. u. Seruminstitut Bram. Separating mixed substances. 16,503. June 21. (Ger., 21,626.)

Hill. Grinding-mills etc. 16,765—6. June 13.

Hole. Condensation product. 16,305. June 20.

Johnson (I.-G. Farbenind.). Treatment of gases with liquids. 16,344. June 20.

Kaiser-Wilhelm-Institut für Eisenforschung. Determining temperature of gases. 16,452. June 21. (Ger., 16,726.)

Krupp Grusonwerk. Apparatus for expressing liquid constituents from materials. 16,395. June 20. (Ger., 23,626.) Apparatus for expressing liquids from materials. 16,474. June 21. (Ger., 20,626.)

Mortrud. Evaporation apparatus. 16,483. June 21. (Norway, 25,626.)

Noppol. Tunnel kilns. 16,841—2. June 24.

Porteus. Mixing, cooking, and drying apparatus. 16,916. June 25.

Ross. Crushers for granular materials. 16,462. June 21.

Thame. Sublimation of volatilisable substances. 16,739. June 23.

Tuckett. Apparatus for drying granular etc. materials. 16,764. June 23.

Vernay. Filtering-apparatus. 16,619. June 22. (Fr., 3,826.)

I.—Complete Specifications

1416 (1926). Frankl. Separation of gaseous mixtures. (246,172.)

4003 (1926). I.-G. Farbenind. Preparing emulsions. (247,588.)

7572 (1926). Fasting. Rotary kilns. (272,616.)

16,348 (1926). Highfield and Highfield. See XXIII.

18,444 (1926). Wiegand. Evaporating apparatus. (272,703.)

21,646 (1926). Camuset. See XVII.

24,113 (1926). Excelsior Feuerlöschgerate. Extinguishing fires. (260,262.)

26,744 (1926). Heskamp. Working shaft furnaces. (272,751.)

26,781 (1926). Caals. Filter cloths. (269,841.)

903 (1927). Amundsen. Production of cold. (266,683.)

1516 (1927). Hase. Optical pyrometer. (272,799.)

*28,193 (1926). Svenska Akkumulator Akt. Jünger. Filters. (272,841.)

*6126 (1927). Industrial Associates, Inc. Spray drying. (272,859.)

*13,638 (1927). Chem. Fabr. vorm. Schering. Manufacture of colourless melted products. (272,875.)

*15,311 (1927). Geigy A.-G. Preparations convertible into dispersions. (272,896.)

*15,854 (1927). Mielck. Continuous treatment of liquids with gases. (272,913.)

*15,982 (1927). Schäfer. Purifying-separator for liquids. (272,927.)

*16,503 (1927). Chem. Fabr. u. Serum-Institut Bram. Separating mixed substances. (272,968.)

II.—Applications

Johnson (I.-G. Farbenind.). Separation of oils from mixtures. 16,346. June 20. 16,347. See III.

II.—Complete Specifications

3984—9 (1926). I.-G. Farbenind. Manufacture of hydrocarbons and derivatives from coal etc. (247,582—7.)

7205 (1926). Patart. Production of liquid hydrocarbons etc. from heavy organic materials. (249,519.)

9861 (1926). I.-G. Farbenind. Manufacture of hydrocarbons etc. from mineral oils, bitumens, etc. (250,948.)

15,504 (1926). Urbana Coke Corp. Apparatus for coking coal. (256,192.)

16,222 (1926). I.-G. Farbenind. Destructive hydrogenation of coal, tar, mineral oils, and the like. (254,713.)

23,527 (1926). Geipert. Testing samples of coal by distillation. (268,718.)

25,316 (1926). Plassmann. Low-temperature distillation of fuel. (260,569.)

26,225 (1926). Still. Coke ovens. (260,974.)

28,894 (1926). Verein f. Chem. u. Metallurg. Produktion. Re-activating decolorising charcoal. (264,799.)

29,398 (1926). Menell. Vertical retort for extracting oil from shale, coal, peat, etc. (272,760.)

32,715 (1926). Humphreys & Glasgow, Ltd. Apparatus for carburetting water-gas. (266,080.)

32,716 (1926). Humphreys & Glasgow, Ltd. Apparatus for making water-gas and other cyclical gas-making processes. (266,681.)

9523 (1927). Nielsen and Laing. Manufacture of illuminating and industrial gases. (272,822.)

12,680 and 13,508 (1927). Manufacture of hydrocarbons and derivatives from coal etc. (272,829-272,835.)

*15,642 (1927). Trautmann. See III.

*16,094 (1927). Silica en Ovenbouw Mij. Coke ovens. (272,942.)

III.—Application

Johnson (I.-G. Farbenind.). Manufacture of hydrocarbons. 16,347. June 20.

III.—Complete Specifications

15,075 (1926). Meiro. Extraction of crystals from anthracene, naphthalene, and like distillates of coal tar. (255,429.)

15,076 (1926). Meiro. Distillation of coal tar, tar oils, etc. (267,074.)

16,222 (1926). I.-G. Farbenind. See II.

*15,642 (1927). Trautmann. Extracting benzene during distillation with scavenging or circulating gas. (272,903.)

IV.—Applications

British Dyestuffs Corp., Ltd., Shepherdson, and Thornley. Manufacture of black and grey vat dyes. 16,731. June 23.

British Research Association for the Woollen and Worsted Industries, and Barker. Testing dyestuffs etc. 16,557. June 22.

Carpmael (I.-G. Farbenind.). Manufacture of dyestuffs. 16,377. June 20.

Deshborough, Knight, and Thomson. Nitration of materials. 16,822. June 24.

I.-G. Farbenind. Manufacture of aliphatic and hydroaromatic sulphonic acids. 16,486. June 21. (Ger., 21.6.26.) Manufacture of dyestuffs. 16,511. June 21. (Ger., 24.6.26.)

Manufacture of amino-alkylanilino derivatives of aromatic amino-oxy and polyamino compounds. 16,752. (Ger., 8.7.26.)

Johnson (I.-G. Farbenind.). Manufacture of dyestuffs. 16,972. June 25.

Scottish Dyes, Ltd., Anderson, Thomas, and Thomson. Production of benzanthrone derivatives. 16,894. June 24. Production of dyestuff intermediates. 16,964. June 25.

IV.—Complete Specifications

6244 (1926). I.-G. Farbenind. Manufacture of azo-estuffs. (248,706.)

6618 (1926). Imray (I.-G. Farbenind.). Manufacture of azo-dyestuffs. (272,580.)

6838 (1926). Leitch & Co., Ltd., and Everest. See XIII.

7197 (1926). Marks (Du Pont de Nemours & Co.). Recovery of antimony in the manufacture of flavanthrone. (272,597.)

13,969 (1926). I.-G. Farbenind. Manufacture of substituted aromatic sulphonic acids. (253,118.)

*15,724 (1927). I.-G. Farbenind. Production of metallic compounds of dyestuffs. (272,908.)

*15,967 (1927). I.-G. Farbenind. Manufacture of dye-stuffs of the anthracene series. (272,924.)

*16,172 (1927). I.-G. Farbenind. Production of dyestuffs containing copper and chromium. (272,949.)

*16,486 (1927). I.-G. Farbenind. Manufacture of aliphatic and hydroaromatic sulphonic acids. (272,067.)

V.—Applications

Czapek. Imparting silk lustre to viscose etc. bodies. 16,500. June 21. (Ger., 8.7.26.)

Food Chillers, Ltd. Waterproofing fabrics, paper, etc. 16,861. June 24. (Australia, 22.7.26.)

Lilienfeld. Treatment of fibrous material. 16,370. June 20.

Melliand. Treating products obtained from vegetable fibres. 16,888. June 24. (Ger., 25.6.26.)

Scholler. Saccharification of cellulose-containing materials. 16,732. June 23. (Ger., 23.6.26.)

Soc. Inoxi. Production of crepe effects on artificial silk threads. 16,551. June 22. (Fr., 14.1.27.)

Weingand, and Wolff & Co. Imparting silk lustre to viscose etc. bodies. 16,500. June 21. (Ger., 8.7.26.)

V.—Complete Specifications

6964 (1926). London Electric Wire Co., & Smiths, Ltd., and Wildy. See XI.

18,727 (1926). Neutrasol Products Corp. Manufacture of artificial silk etc. (255,909.)

21,177 (1926). Wolff & Co., Czapek, and Weingand. Production of artificial silk. (257,925.)

31,264 (1926). I.-G. Farbenind. Production of valuable fibre half-stuff. (264,803.)

31,849 (1926). Allison and Brown. Treating absorbent materials. (272,781.)

*16,080 (1927). Nederlandsche Kunstzijdefabr. Manufacture of artificial textile products. (272,939.)

VI.—Applications

Aspinall, and Aspinall, Ltd. Bleaching fabrics etc. 16,918. June 25.

British Celanese, Ltd., and Cadgène. Dyeing cellulose derivatives. 16,585-6. June 22. (U.S., 30.6.26.)

Ellis (Soc. Fabr. Soie Rhodiaseta). Production of dull effects on fibres. 16,641. June 22.

Food Chillers, Ltd. 16,861. See V.

Johnson (I.-G. Farbenind.). Printing on acetate silk etc. 16,345. June 20.

Pollopa, Ltd., and Spencer. Dyeing. 16,785. June 24.

Rivat. Dyeing cellulose derivatives. 16,585-6. June 22. (U.S., 30.6.26.)

Wakefield. Dyeing fabrics. 16,673. June 23.

VI.—Complete Specifications

7237 (1926). Tom. Impregnation of fibrous materials. (260,540.)

27,718 (1926). Meyer-Sansboeuf Ges. Improving vegetable textiles. (263,102.)

30,344 and 31,731 (1926). Gminder. Treatment of vegetable fibrous materials with mercerising and like liquids. (262,154 and 267,470.)

*16,093 (1927). I.-G. Farbenind. Dyeing. (272,941.)

VII.—Applications

I.-G. Farbenind. Production of anhydrous metal chlorides. 16,761. June 23. (Ger., 13.8.26.)

Jackson (Rhenania Kunheim Verein Chem. Fabr.). Recovery of argillaceous earth from aluminium phosphates. 16,836. June 24.

Schuster. Manufacture of chromic acid. 16,741. June 23.

VII.—Complete Specifications

8500 (1926). Towler and Marsh. Ammonia stills etc. (272,641.)

23,541 (1926). I.-G. Farbenind. Production of phosphorus pentoxide or phosphoric acid. (260,225.)

23,948 (1926). Meyerhofer. Producing metal compounds. (272,733.)

26,166 (1926). Mond (I.-G. Farbenind.). Production of alumina. (272,748.)

27,494 (1926). I.-G. Farbenind. A.-G. Production of cobaltous acetate. (262,075.)

1164 (1927). I.-G. Farbenind. Manufacture of phosphorus and phosphorus oxides. (264,520.)

1850 (1927). Krebs. Apparatus for electrolysing solutions of alkali metal chlorides. (264,865.)

6107 (1927). Dupire. *See* XI.

*29,027 (1926). Omnium des Industries Chimiques. Production of ammonia. (272,842.)

*15,984 (1927). Uhde. Separating ammonia from gases. (272,929.)

*15,985 (1927). Uhde. Synthesis of ammonia. (272,930.)

VIII.—Applications

Corsan. Iridescent glass. 16,905. June 25.

Goldschmidt and Knudsen. Refractory material. 16,581. June 22.

IX.—Applications

Coles. Cement. 16,430. June 21.

Heaton. Manufacture of bricks, tiles, etc. 16,942. June 25.

Johnson (I.-G. Farbenind.). Manufacture of plaster compositions. 16,343. June 20.

Tooth. Compositions for heat insulating etc. 16,539. June 22.

IX.—Complete Specifications

893 (1927). La Trinidad. Manufacture of bituminous or tarry emulsions. (264,497.)

4110 (1927). Eckel. Cement. (268,736.)

X.—Applications

Ashcroft. Metallurgy. 16,866—7. June 24. Separating tin from ores etc. 16,868. June 24.

Johnson (I.-G. Farbenind.). Manufacture of iron. 16,968. June 25. Metallic coatings of chromium etc. 16,969. June 25. Production of iron, nickel, etc., from mixtures. 16,971. June 25.

Jones and Taylor. Material for case-hardening metals. 16,909. June 25.

Metals Protection Corp. Chromium plating. 16,876. June 24. (U.S., 9.9.26.) Polishing chromium. 16,878. June 24. (U.S., 9.9.26.)

X.—Complete Specifications

7445 (1926). Smith. Treatment of metal surfaces. (272,610.)

10,258 (1926). Crowell & Murray Co. Beneficiation of ores. (251,959.)

15,525 (1926). I.-G. Farbenind. Preventing oxidation of magnesium and its alloys. (254,302.)

18,638 (1926). Mond (Goldschmidt A.-G.). Aluminium alloys. (272,706.)

20,904 (1926). Alberti, Thielmann, and Begas. Extraction of zinc from zinc-iron-silicious slags. (259,188.)

108 (1927). Kamishima. Alloy of high specific electrical resistance. (272,788.)

6027 (1927). Lacell. Production of magnesium. (268,316.)

*14,725 (1927). Cholewinski. Bearing metals. (272,889.)

*15,851 (1927). Verein. Stahlwerke. Manufacture of high-grade cast iron. (272,912.)

XI.—Applications

Crood (Jessup & Moore Paper Co.). Electrolytic cells. 16,582. June 22.

Harrison. Electrolytic apparatus. 16,493. June 21.

Parville. Electric accumulators. 16,492. June 21.

IX.—Complete Specifications

6964 (1926). London Electric Wire Co., & Smiths, Ltd., and Wildy. Increasing insulating properties of cotton fibre etc. (272,587.)

27,351 (1926). Felten & Guillaume Carlswerk A.-G. Production of insulating-paper containing phenol resins. (270,243.)

32,181 (1926). British Thomson-Houston Co., Ltd. Electric furnaces. (263,792.)

1850 (1927). Krebs. *See* VII.

6107 (1927). Dupire. Electrolytic apparatus particularly for electrolysing alkali chlorides. (267,912.)

*15,872 (1927). Silica Gel Corp. Electric batteries. (272,916.)

*16,006 (1927). Metallwerk Plansee Ges., and Schwarzkopf. Electrical resistance furnaces. (272,933.)

XII.—Application

Johnson (I.-G. Farbenind.). 16,346. *See* II.

XIII.—Applications

Auer. 16,578—9. *See* XX.

Baly and Baly. 16,784. *See* XX.

Bell and Treleven. Manufacture of luminous paint. 16,371. June 20.

British Thomson-Houston Co., Ltd. Resinous compositions. 16,327. June 20. (U.S., 25.6.26.)

I.-G. Farbenind. Manufacture of coloured compounds. 16,487. June 21. (Ger., 12.8.26.)

Naugatuck Chemical Co. Removing liquid from resinous products. 16,332. June 20. (U.S., 25.8.26.)

Pollovas, Ltd. Manufacture of aldehyde condensation products. 16,783—4. June 24.

XIII.—Complete Specification

6838 (1926). Leitch & Co., Ltd., and Everest. Reduction of pigment colours and lakes to a finely-divided state. (272,585.)

XIV.—Complete Specifications

*7700 (1927). Chem. Fabr. Kalk, and Oehme. Vulcanisation of rubber. (272,860.)

*12,457 (1927). I.-G. Farbenind. Gelatin for light-sensitive silver salt emulsions. (272,867.)

XV.—Application

Du Pont de Nemours & Co. Leather substitute. 16,859. June 24. (U.S., 24.6.26.)

XVI.—Applications

Johnson (I.-G. Farbenind.). Manufacture of fertilisers. 16,970. June 25.

Rhenania-Kunheim Verein Chem. Fabr. Manufacture of fertilisers. 16,331. June 20. (Ger., 28.6.26.)

XVII.—Application

Scholler. 16,732. *See* V.

XVII.—Complete Specifications

21,646 (1926). Camuset. Diffusion plants for making extracts from sugar beet, sugar cane, etc. (258,849.)

*13,866 (1927). Chem. Fabr. vorm. Schering. Manufacture of fructose from inulin. (272,876.)

*16,005 (1927). Elektro-Osmose A.-G. Purifying sugar solution. (272,943.)

XVIII.—Application

Olsen. Manufacture of yeast. 16,523. June 21.

XIX.—Applications

Bellwood. Drying fish etc. 16,272. June 20.

Food Chillers, Ltd. Conservation of meat, eggs, etc. 16,862. June 24. (Australia, 30.7.26.)

Warburg. Preparation of mineral waters. 16,625. June 22. (Ger., 22.7.26.)

XIX.—Complete Specifications

12,637 (1926). Schlotterhose. Production of fish-meal. (272,663.)

25,546 (1926). Macpherran. Dehydrating fruits vegetables. (272,741.)

XX.—Applications

Altenburg and Eichelbaum. Preparations of animal organs. 16,513. June 21. (Ger., 28.7.26.)

Auer. Coagulation etc. of products containing unsaturated carbon compounds. 16,578. June 22. Altering aggregation of products containing unsaturated carbon compounds. 16,579. June 22.

Baly and Baly. Manufacture of aldehyde condensation products. 16,784. June 24.

I.-G. Farbenind. 16,486. See IV. Manufacture of cyclic ketones. 16,846. June 24. (Ger., 24.6.26.)

Pollopos, Ltd. 16,783-4. See XIII.

XX.—Complete Specifications

31,955 (1925). Macewen. Manufacture of solution of derivatives of dioxidiamino-arsenobenzene. (272,567.)

12,997 (1920). Casale. Preparing alcohols and other oxygenated organic compounds. (252,713.)

15,427 (1926). Heyn. Production of salts of amino-guanidine or amino-alkylene-guanidines. (272,686.)

*10,646 (1927). Commercial Solvents Corp. Catalysts for synthetic methanol production. (272,664.)

*15,954 (1927). Böhme A.-G. Rendering higher alcohols soluble. (272,919.)

*15,966 and 16,179 (1927). Consort. f. Elektrochem. Ind. Manufacture of acetic anhydride. (272,923 and 272,951.)

*16,486 (1927). I.-G. Farbenind. See IV.

XXI.—Complete Specifications

27,200 (1926). Didier. Three-colour photography. (272,754.)

*15,968 (1927). Devienne. Toning and fixing of photographic prints. (272,925.)

XXII.—Applications

Desborough, Knight, and Thomson. 16,822. See IV.

Imperial Chemical Industries, Ltd., and Alexander. Explosives. 16,362. June 20.

XXIII.—Complete Specifications

3315 (1926). Beck, and Deutsche Gold- und Silber-Scheideanstalt. Destroying animal pests. (272,570.)

16,348 (1926). Highfield and Highfield. Treatment of feed-water for steam boiler plants. (272,693.)

*15,508 (1927). Jamotte. Combustible disinfectant, antiseptic, or parasiticide product. (272,900.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number: *Argentina*: Steel (A.X. 4846). *Australia*: Chemicals (648). *British India*: Process chemicals, chemicals (650); galvanised corrugated mild steel sheets, glass, steel tyres (Director General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1). *Denmark*: Glazed pipes, fireproof materials, roofing (654). *Germany*: Oils (lubricating, textile and leather), paraffin wax (657). *Holland*: Copper tubes, condenser tubes (663). *Italy*: Copper sulphate (664). *South Africa*: Spring steel (A.X. 4841); Steel lighting poles (A.X. 4842); steel bars (A.X. 4838). *Spain*: Essences for perfume manufacture (666). *Syria*: Artificial silk yarns (671).

Uncompounded Drugs and the Merchandise Marks Act, 1926

The Board of Trade has exempted uncompounded drugs, from whatever source derived, which are sold for medicinal purposes, from the requirement that imported goods bearing a British name or trade mark must also bear an indication of origin. The exemption does not apply, however, if the drugs are sold or exposed for sale under a proprietary name.

News from Advertisements

1. The Egyptian University, Cairo, requires a glass blower (p. x).

2. An assistant chemist is wanted for petroleum refinery in India (p. x).

3. One or two academically trained chemists, preferably with experience in the manufacture of acetic anhydride, are wanted (p. x).

4. A food factory in South London is advertising for a laboratory assistant (p. x).

5. The Royal Technical College, Glasgow, again announces particulars of the forthcoming session (p. x).

6. Viscose chemist (lady) requires a laboratory or plant appointment (p. x).

7. An organic chemist and chemical engineer seeks technical or business appointment in the London area (p. x).

8. Second-hand Redwood Viscometer and other instruments are wanted (p. x).

9. Several volumes of various chemical journals are required (p. x).

10. A technical chemist is required for a situation in the East (p. x).

11. There are 96 firms using the Buyers' Guide in this issue of CHEMISTRY AND INDUSTRY (p. x).

LONDON, JULY 15, 1927

No. 28

EDITORIAL

Trypanocides

THE progress of the British dyestuffs and fine chemicals industries has amply justified the measures of protection which have been afforded during the past few years. The quality, range of production, and price levels arranged demonstrate that there has been no abuse of the confidence placed in the manufacturers, who have striven in every way to meet the natural desire of the consumers to buy in the cheapest market, and the fact that 80% of the British requirements for dyestuffs has been met for some time from home factories stands in strong contrast with the pre-war position. The general acquiescence of the dyestuffs industry in the new price factor decided upon by the Dyestuffs Advisory Licensing Committee provides the latest evidence of the determination of the industry to face foreign competition boldly. British fine chemicals are winning a splendid reputation throughout the world, and the quality of British research in this field is surpassed nowhere. British-made insulin is recognised abroad as second to none, and is finding acceptance even in Germany and in former German-fed markets, whilst the story of real progress in its production and consequent price reductions has often been told. Borocaine, a synthetic local anæsthetic with special advantages over cocaine, and synthetic anæsthetics such as eucaine, is still a comparatively new product. Synthetic thyroxin came upon the market in a remarkably short space of time after its constitution had been determined and its synthesis so brilliantly achieved by Harrington. Similarly, intensive work upon the question of the irradiation of cholesterol and its associated sterols was rapidly followed by the commercial production of an irradiated ergosterol, which supplies for the first time an artificial vitamin D preparation of amazing potency.

Ever since Ehrlich blazed a trail into the unknown country of chemotherapy, German, French and British chemists have been seeking a synthetic remedy for the scourge of sleeping sickness, but success has been largely denied them until, a few years ago, Bayer 205 was produced. Still more recently Fourné made his com-

pound No. 309. It is gratifying to note that fundamental work is still proceeding in this country upon the relation of chemical constitution to trypanocidal power, as is shown by the appearance of Part VI of King's investigations in the current number of the Journal of the Chemical Society. It will be remembered that it was King who suggested that the secret Bayer 205 was probably made by the action of carbonyl chloride upon the amino derivative of a substance produced by the twofold introduction of *p*-nitrobenzoyl chloride into the molecule of H acid. That this suggestion was near the mark was proved by the synthesis of Fourné 309, which appears to be closely allied to the German preparation, but in which *p*-nitrobenzoyl chloride and 2-nitro-*p*-methylbenzoyl chloride are employed in place of two molecules of the former benzoyl derivative.

Perhaps two of the most important series of trypanocidal drugs are those which contain the phenylarsenic acid grouping and a naphthylaminesulphonic acid grouping linked with one or more aminobenzoyl residues, and it has been the bold conception of King and his co-workers, amongst other things, to prepare compounds containing at one and the same time these two potentially powerful groupings. The series of complicated researches already reported has revealed a masterly grip of the science of organic synthesis and makes fascinating reading, although it is to be regretted that as yet no compound has shown the trypanocidal powers of the Bayer or Fourné preparations.

The complexity of the syntheses recorded may be gauged from the following broad outline. In the first place the three *ortho*, *meta* and *para* aminobenzoyl-*p*-aminophenylarsinic acids were prepared, and by a repetition of the process of nitro-benzoylation and reduction of the nitro groups to amino groups, further aminobenzoyl groupings were added. The number of compounds possible is very large, and many have been prepared and examined in regard to their trypanocidal activity, and the work has been still further extended and elaborated by the preparation of symmetrical carbamides with the aid of phosgene. Unfortunately, however, amongst the trinuclear compounds prepared,

the only one which had any curative action upon trypanosomiasis was *p''*-aminobenzoyl-*m'*-aminobenzoyl-*p*-aminophenylarsinic acid which, in a dose of 0.175 mg., caused the temporary disappearance of trypanosomes from the animals experimented upon, but relapse occurred relatively soon. Again, with the aid of phosgene, such a compound as that just indicated can be duplicated in a symmetrical carbamide, and many carbamides, clearly of very high molecular weight and representing arsenical preparations of the greatest known complexity, have been made, but whilst of extreme interest in many ways, they are comparatively inapplicable as trypanocides.

Further complications with regard to the amphoteric nature of possible curative preparations have been studied, as yet without avail, but the elaborate programme is not yet at an end and, with the recollection of Ehrlich's six hundred and five unsuccessful preparations which had to be made and tested so unwearyingly before salvarsan or "606" was given to the world, we may in all humility counsel the British workers to persevere until ultimate victory crowns their magnificent efforts.

The Cure of Sleeping Sickness

The value of a successful curative drug for the scourge of sleeping sickness can scarcely be overestimated, particularly in its incidence upon the development of the tropical parts of the Empire. Small wonder, then, that the merits of Bayer 205 should have received careful scrutiny at the hands of experts. It is known that the chemotherapeutic index—that is, the ratio of the minimum curative dose to the maximum amount tolerated by the animal under test—of Bayer 205 is as low as 1 to 160, a figure which contrasts markedly with the 1 to 2 ratio of such a preparation as atoxyl, one of the early trypanocidal drugs. Fournier's compound shows an index which is as low as or lower than that of the German preparation, and we shall hope to hear more of its practical value. All we know up to the present is that remarkable cures have been effected with the aid of Bayer 205, as has been shown by the reports of the Medical Expedition sent out under the auspices of the British Colonial Office. Another disease of the sleeping sickness type which affects horses in South America, has been successfully treated with Bayer 205. Similarly, sleeping sickness in horses and cattle in Malaya has been cured in 50–75% of the cases kept under observation. In this country, it is recorded that seven out of nine human beings suffering from sleeping sickness, *T. gambiense*, were cured. Again, 200 cases of sleeping sickness in South African natives have been successfully treated with the German preparation, and even where the central nervous system was affected the remedy has not been without result. Much remains to be done both in the preparation of more powerful trypanocides, and in their full testing out and application.

Bathos, Alternate Polarities and China

A valued correspondent has accused us of that sinking sensation, bathos: it is probably true: we have been accused of worse crimes, even flippancy, but to this we plead not guilty. What our correspondent calls bathos we consider accuracy. Every time that prolonged meditation calls forth some noble sentiment and sonorous

phrase, the still small voice of reason calls upon us, in the near future, sometimes even the next sentence, to counteract the exaggeration and discount the premium. This is typical of the structure of man's mind, and of many other organic substances; they are divided into layers, probably concentric, which correct each other's exuberance or poverty; if the one layer soars above the average, the next layer will sink below it, for the law of truth, the average, the neutral state, will ultimately prevail. A section through the human mind would therefore show a sinuous curve, resembling a snake in the grass, the forked tongue of which is followed by harmless coils, and these by the sting in the tail. As a matter of fact, the sting is comparatively rare in modern snakes, and the nearest approach to it is the rattle. This, again, is typical of the editorial mind. If a man is modest of his achievements, who can say whether this is modesty or vanity? There is no vanity so pernicious as the conscious understatement of our abilities. And yet the man may recognise this fact and descend to a philosophical level which is indifferent to both the affectation of vanity and the affectation of modesty. This desire to counteract the excess is the true explanation of alternate polarities in chains of carbon atoms and of the bathos which a casual observer may detect on the surface layer of some of our editorial effusions. Action and reaction are equal and opposite. It is the extreme Socialists who are the main strength of the stern unbending Tories: it is the latter who are the main cause of the Socialists. When Mr. Edwin Thompson enlivened the proceedings at the Society's banquet in Edinburgh by a bright and amusing speech, which could be easily heard throughout the hall, he afforded another instance of this sort of alternation of the vehement and the quiet, the positive and negative. We wrote an editorial in April in which we alluded to China. The information at our disposal was then obviously a few days—perhaps even two or three weeks—old, and we are informed now by residents in China that we have given a wrong impression of the state of affairs. As we have no wish to do this, we take this, the first, opportunity of publishing our correspondent's corrections, which have taken a few weeks to reach us. They inform us that the labour situation is very serious, and is causing very grave concern to employers, and that the ideas we had about Shanghai are not in accordance with the facts. The river frontage of the French concession and International Settlement is about six miles, and the area of these two is about fifteen square miles: the resident foreign population is 38,000 and the resident Chinese population 1,100,000. The tramways, electricity department, and waterworks company are huge concerns with a capital running into several millions; that, though the factories in the Shanghai area were working at nearly normal capacity in the large area then occupied by the Cantonese Army, most of the factories were closed down, and many have been utterly destroyed. To what extent some of the other statements in our correspondent's letter have been modified during the last five weeks we do not know, but we think that reactions have taken place in that country also. Whether alternations have taken place or not, we have no desire to place misleading information before our readers, and are always grateful to those who help us to greater accuracy.

THE ANNUAL MEETING

There is no doubt that the Edinburgh meeting has been a conspicuous success. It was well attended, about four hundred took part in it, though comparatively few stayed from the beginning until the very end. We missed a number of those who have held high office in the Society and have been constant in their attendance at these meetings, for instance Sir William Pope, Dr. E. F. Armstrong, Mr. W. J. U. Woolcock, and Dr. Levinstein, various engagements and other causes prevented these from coming, so too Prof. H. E. Armstrong, M. Agache, Dr. Fourneau, and some others who, we hoped, would be present. Our ex-president, Prof. Louis, recently nominated as President of the Institution of Mining Engineers, had to leave before the meeting was concluded, so had our ex-treasurer, Mr. E. V. Evans, and our ex-member of Council Mr. Emile Mond, replete with the best products of Princes Street and with recollections of Loch Katrine. On the other hand, many old friends and young friends came early and sat up late and were loth to go home. We were glad to welcome Dr. Kurt Meyer and Frau Meyer; Dr. Meyer's excellent speech at the dinner was received with enthusiasm, and we shall hope for his presence at our future meetings and to listen to other speeches of his, equally well-phrased, equally full of matter, and equally brief.

The Edinburgh meeting left a rather confused impression on our minds: there was so much to do, and see and say, and listen to, and all of it very good. We came away with mingled recollections of the Presidential address, Col. Pollitt's address, the beauty of Edinburgh and the surrounding country, the local patriotism of the Scots, and the skill and enthusiasm of the local committee, and in particular the chairman and secretary, who had organised most successful papers, discussions, visits, receptions and dances. We have already written on the address of the President, while his words were still fresh in our mind, but before we had any opportunity of reflecting upon them. The distance of Edinburgh from London compelled us to write with the utmost speed of which we are capable, and we were, in consequence, unable to indicate how excellent and how well written his address was; fortunately the paper is already published, and speaks for itself.

Colonel Pollitt looked at his subject broadly, and spoke of it as some black-and-white artists draw pictures, giving us the essential features surely and simply with no unnecessary frillings and no redundancy of thought or word. His industrial schemes are too broad to be conceived by any narrow mind, he "makes one city of the universe, where some may gain and all may be supplied." We feel sure that all our readers will profit by his address; it deserves a far wider audience. One of our writers told us recently that Carlyle had a bad digestion and mistook it for a deranged universe; Col. Pollitt, on the other hand, can see the universe as it is, and frame his plans accordingly, down to all the essential details.

Many volumes have been written about Edinburgh, Melrose, Abbotsford, and the Trossachs; many more

could be written, and still the subjects would not be exhausted; there never were any other city and district which, naturally beautiful, have by the lapse of years and by historical, romantic and literary associations from ancient to modern times, become so full of charm. It is no mere chance arrangement: no atoms casually together hurled, could e'er produce so beautiful a world; from the Castle yard we saw Edinburgh and the Firth of Forth at midnight: we saw Loch Vennachar and Loch Earn during alternations of rain and sunshine; we intended to see much more, and have the intention still firmly fixed in our minds. The civic reception was full of interest, the robes of the Lord Provost, the bairns, the councillors and the attendants took us into the mediæval past, and it was a delight to see the Solemn League and Covenant and the many relics of Scott, Burns, Ferguson, and other famous men. It is worth while to leave the smoke, the wealth, the roar of London, and the bustling street, in order to see the quiet of Holyrood, and the peace that is among the lonely hills. The Scots have every reason to be proud of their capital, their country, their history, their poetry, and their songs, and they are proud of them; they are a singular mixture of hard heads and soft hearts; they are full to the brim of sentiment, and sentiment is so often false. Bonnie Prince Charlie, even the whole house of Stuart, did not deserve the beautiful Jacobite songs written about that unhappy ill-fated cause, the sentiment of which persisted long after it ceased to be a practical piece of politics. It was a lost cause in 1715, when the Earl of Derwentwater lost his head: folks said it was na a very good one, but it was a sair loss to the poor gentleman; it was a lost cause in the '45, and only an outrageous love of sentiment could have kept alive in many people until the end of the century a dream, a hope, which they knew would not be realised, of a restoration of the Stuarts. We now reap the benefit of this sentiment, we wander about in a real, handsome city with railways and chemical laboratories, and the whole place is pervaded with a remembrance of old, unhappy, far-off things, and battles long ago.

The local chairman, the local secretary, and the local committee did their arduous and pleasant work extremely well; there was enough organisation and not too much: it is quite possible to have too much; we are not cogs in a machine, but human beings. We praise the Edinburgh Section on this occasion, and they fully deserve all the praise which we and others can offer to them: they are the obvious people who should be praised, and yet we think they will not consider us as grudging in our meed if we say that the chairmen, secretaries, and members of all the local committees, group committees, and so on form a body of highly loyal and conscientious workers who rightly believe in the Society, work for it, and are sincerely attached to it. We know how pleasant it is to work for the Society, and how happy a family we are; we are perhaps inclined to forget, some of us, how much work and devotion are given by all those who take on their shoulders the organisation of the papers and meetings of the Society; if we are inclined, ourselves, to

place on the highest plane the work of the many secretaries the reason is obvious; we once occupied the position of a local secretary. The Society of Chemical Industry has given life to chemistry: the earliest chemist wrote, many years ago, "He is not dead who has given life to science." Like the lad who was half buried in the ruins of a house in the High Street of Edinburgh, the Society is no dead yet.

The Luncheon

After the Annual Meeting a luncheon was given, by invitation of the Edinburgh and East of Scotland Section. Mr. W. A. Williams was in the chair.

After the loyal toast, Dr. Angus MacGillivray, in welcoming the Society on behalf of the University of St. Andrews, observed that his first duty was to offer, on behalf of Principal Irving, his very great regrets at not being present at this meeting. Principal Irving was known to those present as a distinguished chemist. To his colleagues around the University Court he was known as a brilliant administrator. When he was appointed he was a very young man. He was a scientist, and not a theologian, but his conduct in the chair at St. Andrews justified in every way his appointment, and it was safe to say that youth and a scientific training were no bar to the office of Principal and Vice-Chancellor of a Scottish University. Dr. MacGillivray then described the history of the teaching of chemistry at St. Andrews since 1840, and said that St. Andrews University on either side of the Tay was worth seeing and worth going to see, and he hoped they would take the welcome that had been offered to them.

Prof. Alexander Findlay said that, like the previous speaker, he had to commence by expressing the regret of the Vice-Chancellor and Principal of the University of Aberdeen that, owing to his many university duties at this time, he was unable personally to offer the Society a very hearty welcome to Scotland. Although Aberdeen University had not been associated directly with the teaching of industrial chemistry, the principles of chemistry had been taught from a very early period in the two independent universities which existed and flourished within a mile of each other. The time was not very far distant when it would have appeared almost inconceivable that the university should be glad to be associated with and to welcome a Society the main aims of which were industrial. Those unhappy days were fortunately past. We now all were glad to realise that those who pursued pure science, believing that it itself alone shall be its reward, and those whose interests lay mainly in the industrial applications of science, now marched forward in happy and fruitful co-operation, and we recognised that pure and applied science act and react upon each other most beneficently. We had learned that there would be no application of science unless that science already existed to apply, and we were now also learning, but had not yet perhaps fully learned, that the problems of industry gave a stimulus to purely scientific research which resulted in discoveries of the highest theoretical interest and industrial and economic importance. Because this Society, with its large membership, pursuing and promoting both pure and applied chemistry, showed in such a high degree the spirit of co-operation, the University of Aberdeen bade it heartily

welcome. There was another reason why they welcomed it to Scotland. This Society was doing a noble work in preserving the humanity of industries. These annual meetings enabled chemists to come together in social intercourse, and he believed—and perhaps most of them recognised—that that was a matter of the very highest importance. Those who worked and lived in centres of large industry could not understand and appreciate the feelings of loneliness and forlornness which assailed those who were loyally keeping the flag flying in small provincial and outlying areas; and it was no wonder that sometimes, especially among the younger chemists, the earlier enthusiasms should begin to die out. Now, these annual meetings gave a golden opportunity to all such chemists of coming and spending a happy week in social intercourse with others of like interests, of exchanging ideas, and of refreshing their minds in an atmosphere of active endeavour and scientific achievement. He sometimes wished, as a chemist, that the Chemical Society would imitate this Society in holding such gatherings as the present. Because of the humanity and good comradeship of this Society of Chemical Industry, the University of Aberdeen extended to it a very hearty welcome to Scotland. It was not the first time it had been in Scotland; the University of Aberdeen hoped it would not be the last.

In reply, Mr. Francis H. Carr, C.B.E., the President of the Society of Chemical Industry, said it was indeed a disaster to have to follow two such eloquent speeches; but the sincerity of those speeches transcended even their eloquence. We in the Society of Chemical Industry appreciated and knew that knowledge, and knowledge of our art, was the one method of our progress, and that our knowledge we gained by close and perpetual contact with the universities of this country. Therefore it was an especial pleasure to the Society to come to Edinburgh, where three great university centres brought their rays to focus on one point and came to welcome us in the way they had welcomed us. It was thought, after all, which was the impulsive force of industry, just as it was of the purely academic study. We kept alive by progress, and our progress resulted entirely from thought; and it was the raw material which universities produced which gave industries their force and capacity. The most important raw material that we had to handle was the human element produced by the universities. And therefore he felt that, in acknowledging this welcome, he ought at the same time to express the indebtedness of chemical industry to the work of the universities in providing this raw material. With all sincerity and in the most genuine spirit, he returned, on behalf of the Society, very cordial thanks for the welcome they had given it.

In the afternoon a garden party was held in the Zoological Park. The proceedings were interrupted by a heavy downpour, but in compensation the animal houses provided much interest and amusement. In the evening there was a reception by the President in the Palais de Dance, Fountainbridge, followed by a dance which lasted until 1 a.m.

The proceedings on Wednesday opened with a joint meeting with the Biochemical Society, to discuss "The physiological and industrial aspects of the chemistry of

carbohydrates." Professor Barger, F.R.S., was in the chair. The papers read at this meeting will be found in this issue as well as in that of July 8.

At the same time, the Chemical Engineering Group held a meeting under the chairmanship of Mr. F. Heron Rogers, M.I.Mech.E., M.I.Chem.E., to hear a paper by Dr. J. L. A. Macdonald, D.S.O., on "Some aspects of the manufacture of fibrous cellulose" (cf. this J., July 1, 1927, 251T). The paper was followed by the projection of a kinematograph film showing the production of esparto paper, for which thanks are due to Mr. W. Harrison, LL.B., chairman of the Inveresk Paper Co., Ltd. The meeting was followed by a luncheon, held in the University Union.

On Wednesday afternoon, two parties were formed, one going to the University Chemical Department to hear Professor Read lecture on "Natural sources of energy in Australia" (cf. CHEM. & IND., July 8, p. 613), and then to visit the University Chemical Laboratories.

The University Chemical Laboratories

Much could be written about the visit, on July 6, to the University chemical laboratories, which occupy a delightful situation some little distance from Edinburgh, and share with the Eugenics Department a position on a site of slightly over 100 acres, which has been purchased by the city, and will be further developed as required for use. The party on its arrival was met and given a cordial welcome by Prof. Sir James Walker, who conducted it to one of the lecture theatres, where a most interesting discourse (with lantern slides) was given by Prof. J. Read (University of St. Andrews) on "Natural sources of energy in Australia," after which Sir James Walker gave a brief account of the building, and then divided the party into groups, which, accompanied by members of the University, made a tour of as much of the building as was permitted in the limited time at their disposal. The Chemical Department is a long low building, mainly one storey high, traversed by a central passage, into which most of the rooms, which are lofty and well lighted, open: four lecture rooms are together, and open into one centrally-placed "preparation room" from which all are served.

Economy of space, utility, and freedom from useless ornamentation are the dominant keynotes, the interiors of the walls are unplastered, and the exposed red bricks of which they are built give an air of simplicity often foreign to laboratories. The lecture rooms are lighted by vertical windows placed in the sides of a chamber opening from the centre of the ceiling, and when required the room can be completely darkened by pressing a button, when the whole upper chamber sinks, and its roof completely closes the orifice in the ceiling of the lecture-room.

In addition to everything necessary for tuition and research in pure chemistry, there is a department devoted to the methods of the technologist; this contains evaporating and distilling plant, filter presses and autoclaves of a size suitable for working on a small industrial scale, intermediate between that of the laboratory and the mass production of large works. The usual services of gas, water, steam, and so on are laid on, and a spirit of mobility is maintained whereby "plant" can be

"shifted" as required, thereby making for economy and allowing a diversity of operations being readily carried on. Thus, the students trained in this University who wish to take up an industrial career should start their work with greater assurance to themselves and satisfaction to their employers than if they had previously handled only laboratory apparatus.

The Edinburgh Corporation Gas Works

The other party drove to Granton, to visit the Edinburgh Corporation Gas Works. Over 100 members were taken in chais-à-bancs to the works, and were met by Judge Harvey, the convener of the Gas Committee, and his wife, supported by Mr. Alexander, works engineer, Mr. Scott, chief chemist, and a number of assistants. The party was divided into six groups. Judge Harvey, in welcoming the party, expressed his pride that the Society should have selected Granton for a visit, when there were so many other interesting industrial concerns to see in the Edinburgh District. He felt that they had one of the most up-to-date carbonising plants in the country, and was sure that there would be much of interest to see. Dr. E. W. Smith thanked Judge Harvey and the Gas Committee for their kindness in welcoming them there, and commented on the fact that in Granton they had a works which, architecturally and from the point of view of layout was incomparable, and a pattern for other gas undertakings.

During the course of the inspection each party was shown the retort house, containing a large installation of Woodall-Duckham continuous working vertical retorts through which already over 230,000 tons of coal had been put.

It was notable that the plant was so clean in its working that ladies amongst the party were able to go from top to bottom without in any way spoiling their apparel. From the point of view of smoke and dust there were no signs that anything was going on in the retort house. The exhauster house, water-gas plant, purifier house, meter house, and laboratories were also inspected.

Mr. Gracie, the Engineer and Manager, was unfortunately unwell, and was unable to be present, and Mr. Jamieson, his assistant, was away on holiday.

Both parties met later on at the reception, held by invitation of the University Court, in the Upper Library Hall, in the Old University Buildings. The guests were received by Professor and Mrs. G. Baldwin Brown. Professor Baldwin Brown, who is Senior Professor in the University and Professor of Fine Art, delivered an eloquent discourse on the historical and artistic interest of the City, which was much appreciated by the guests. Mr. F. H. Carr, the President, responded on behalf of the Society.

The Annual Dinner

The Annual Dinner was held within the North British Station Hotel, Edinburgh, on Wednesday, July 6. The President, Mr. Francis H. Carr, C.B.E., was in the Chair.

The Chairman, in proposing the toast of "The City and University of Edinburgh," said the Society of Chemical Industry was holding its annual meeting in a town which was unique among the towns in which the

Society had sections. It was unique in very many respects, which many had discovered to their delight in the last few days, but it was also unique in respect that in proposing the toast of "The City and University of Edinburgh," he was confident that in associating the town and gown he was doing what they themselves would have chosen as the toast of the evening. Edinburgh was and had been for a long time the centre of the highest art of government in Scotland, a very important centre of education for the whole of Great Britain, and an exceedingly important centre for Scotland. They in the Society of Chemical Industry particularly appreciated the opportunity of being associated with education. It was their business to make use of the product of education to promote the health, the happiness, and the prosperity of the citizens of their great country. The Society was in many respects like a university, for it constituted a sort of post-graduate course of learning which all of them carried on throughout their lives. They made it their business in the Society to disseminate knowledge, classify knowledge, and promote research, and the atmosphere of Edinburgh could not be more congenial or more inspiring in that respect. They had come to a city where long vistas, not only those of the eye but those of the mind, were ever before them. They carried them back through centuries; and what to them was equally important, they looked discerningly into the future. The application of chemistry to industry demanded that chemists really had to continue their education throughout life. The reason of the success of the Society, the very reason for its existence, was they regarded themselves as an educational institution. Their work called for ability in science, ingenuity in experience, and discovery of the facts which it was their duty to apply. The wonderful position which the chemical industry had attained in this country was in very large measure due to the work of our Society, and that tradition could not have been attained unless they had fostered education. During recent years they had aimed in the industry for greater achievement and greater efficiency, and they had argued as to how they could possibly obtain that working together for efficiency by which alone they could make themselves the first, or amongst the first, in the world. Since the last meeting of the Society the different branches of the chemical manufacturing industry had joined together in a united effort to render the whole industry efficient. All this came, in his opinion, from the fact that they as chemical industrialists paid homage to universities and tried to bring the universities into close relation with the principal affairs of their life, and it was that spirit in which they found themselves in Edinburgh, which gives him so much pleasure in proposing the toast of the City of Edinburgh and the toast of the University of Edinburgh in one. For the enjoyments and luxuries they had enjoyed, and the hospitality that had been extended to them, they were indebted to the City, to the Chamber of Commerce, and to the University and its Vice-Chancellor. They were indebted also to the Edinburgh Section of the Society of Chemical Industry, and they were indebted to Mr. Williams, the Chairman of the Local Section, and also to Dr. Williamson. The President then gave the toast of "The City of Edinburgh and the University of Edinburgh," coupled

with the names of my Lord Provost, Professor Barger, and Mr. Williams.

The Lord Provost (the Right Hon. Alexander Stevenson), replying to the toast, said it had often been his privilege to reply to the toast of "The City of Edinburgh," but this was the first time he had been called upon to reply to that toast in conjunction with the University of Edinburgh. Personally, he welcomed the innovation, because between the University of Edinburgh and the Corporation of Edinburgh the relations had always been of the most friendly character. He wished to thank the members of the Society for the compliment they had paid them in holding this conference here. He understood that they were going to America next year, the land of big things, but he was satisfied that they would go to no town or city of the New World that would appeal to them as the City of Edinburgh. Many might think that Edinburgh was a mere "show" city, but he wanted them to realize that they were trying to make Edinburgh not only a city of education, but an industrial city. The Society, in its way, had been doing well, not only in promoting research, but in showing what science could do in the field of industry. He only wished that employers and employees throughout the country would also play their part and recognise that their interests were not antagonistic, but were identical. Then would science be on the one hand and peace on the other, and then we would have that revival of trade for which we were all looking. He had to return thanks for the way in which the toast had been proposed and received.

Prof. G. Barger, F.R.S., who replied for the University, said the duty should have been laid on the broader shoulders of his senior colleague, Sir James Walker, or, alternatively, it should have been entrusted to the Principal of the University, Sir Alfred Ewing, but these gentlemen were absent, and the duty of acknowledging this toast devolved upon himself. It was very appropriate that the University should have been associated with the town in this matter, for the association was one of long standing. He thought the University would welcome now, in its reformed condition, a somewhat closer association than heretofore—an association of the kind such as obtained in Manchester or Birmingham; for they would know full well how expensive it was to run a modern laboratory, particularly a chemical laboratory. They had visited the laboratory to-day for which the University had made great sacrifices; indeed, this laboratory, which was a severe strain on the University, was in very bad odour with his colleagues of the Faculty of Arts—in worse odour than chemical laboratories in general.

Mr. W. A. Williams, associating himself with the reply, said he was not included on the official toast list, but the President had kindly included the Edinburgh and East of Scotland Section in the toast generally with the City and the University of Edinburgh. He thought this far too great an honour, and he felt covered with confusion by all the nice things that had been said, not only by the President, but also by Prof. Barger, and he felt sure the whole of the members of the Section must feel the same. Speaking for the Section, they felt it was their duty to do all they could. Mr. Carr,

in his opening address, said that on previous occasions when the Society had been here they had taken something back with them. On this occasion they hoped that all the members would take back a lasting remembrance and a pleasant remembrance of their short week here.

Dr. W. T. H. Williamson, Hon. Secretary of the Edinburgh Section, briefly associated himself with the reply.

Mr. Edwin Thompson, proposing the toast of "The Guests," remarked that in the time available it was impossible to mention all the guests, but he would like to mention two names on the toast list, namely, Lord Salvesen, who had honoured them by coming, and, as it were, representing the majesty of the Law; also he wished, on behalf of the members of the Society of Chemical Industry, to extend a very genuine and sincere hand of friendship to Dr. Kurt H. Meyer, who had come over from Germany to attend this meeting.

In his reply, Lord Salvesen said he had been interested in chemistry all his life. More than fifty years ago he was a student of the then Professor of Chemistry, and he also then attended the laboratory of an analytical chemist and learned the elements of analytical chemistry. There was no part of his general education that had been more useful to him than a knowledge of elementary chemistry. In his professional life he found it invaluable, not merely in patent cases, but in many other cases. But what had struck him more than anything else was the colossal ignorance of the elementary facts of chemistry which prevailed throughout modern society, and yet chemistry touched life in a way no other science did, and even the housewife would, he thought, be very much better if she knew a little with regard to chemistry. He had to thank them very much for having done him the honour of asking him to be one of the guests.

Dr. Kurt H. Meyer, in acknowledging the toast, said he had to bring also the thanks of the society which he represented, the German Chemical Society, for their kind invitation, and he had to transmit the greetings of that society. It was a particular pleasure to him to join the meeting, because it gave him the opportunity to express his deep respect of British Chemistry, and especially of his master, a Scotsman, the late Sir William Ramsay. He was a student at the University College, London, and what he learned there had had a great influence on his chemical career. Ramsay was a student of a university in Germany, and was a great friend of many of his German colleagues, and he (the speaker) hoped that many of his connexions might be re-established and never ended again. The best way to know one another and to comprehend each other, and to make acquaintance with each other, was to get to know people's ways and manner, and a better understanding between peoples and nations was what we needed in Europe.

The Dean of Faculty (J. Condie Sandeman, K.C.) proposed the health of the chairman, and the chairman briefly replied.

During the evening a Scottish musical programme was given, and the dinner was followed by a dance.

Thursday's proceedings were distinguished by the lecture delivered by the Society's Medallist, Lieut.-Colonel G. P. Pollitt, D.S.O., on "The development of the synthetic nitrogen industry in Great Britain." The lecture, which is dealt with elsewhere, is printed in "Transactions" in this issue.

For fuel technologists the remainder of the day was occupied by the Coal Cleaning Conference, held under the joint auspices of the Fuel Section of the Society, the Institution of Gas Engineers, and the Coke Oven Managers' Association, Dr. C. H. Lander presiding. All the papers read have been published in "Transactions"; and the discussions will be dealt with later.

Interesting excursions were arranged for the Thursday afternoon, different parties going to the paper mills of James Brown & Co., Ltd., Penicuik, and to the works of the North British Rubber Company, Ltd., whilst those who were not industrially inclined were able to join a conducted tour of old Edinburgh.

Visit to the Paper Mills of James Brown & Company, Limited

Many of those who had, on the previous day, viewed with interest the film dealing with the manufacture of paper from esparto grass were able, through the kindness of Major William Jardine, O.B.E., of Eskmills, Penicuik, to see the actual processes in operation in the paper mills of James Brown & Co., Ltd.

Leaving Edinburgh about 2.30 p.m., the party of sixty members braved a genuine Scotch mist during the drive to the works, which are situated in the deep valley of the North Esk, some ten miles inland. Upon arrival, the visitors were met by Major Jardine, and then in small parties commenced their tour under the guidance of the works staff.

The raw material, esparto grass from Africa and Spain, first claimed attention, and the preliminary operations of breaking up the bales, removing dust and feeding into the digesters having been seen, the maceration and washing of the alkali cooked cellulose was followed. Next came the bleaching and further washing of the now snowy pulp, which, after a considerable amount of further beating and the addition of binding materials, was ready for the actual paper-making machines.

Undoubtedly the most fascinating part of the whole process was next revealed. The still fluid pulp, flowing smoothly on to a wide, slowly-moving, endless gauze of fine wire, whereby the excess of water was rapidly drained away, became in the space of a yard or two a cohesive ribbon, some few feet broad, strong enough to be gathered up by the blanketed rollers which passed it endlessly on to the heated revolving drums for drying.

An added interest was felt when it was explained that the machine was actually making paper for the JOURNAL of the Society, and doing so at the rate of three tons in the working day. After the paper-making itself, were shown the subsidiary processes of glazing and burnishing special papers, and finally the cutting up and examining departments were inspected.

The company was entertained to a very enjoyable tea in the works. Prior to leaving, Mr. Edwin Thompson thanked Major Jardine for his kindness in allowing the

party to see the works and for the interest he had shown in the visit. Major Jardine, in reply, said he had been honoured to have the members of the Society there.

The Works of the North British Rubber Co., Ltd.

Another large party was taken to the Castle Mills to inspect the operations of the North British Rubber Co., Ltd. The party was divided up into groups which made a tour of the laboratories and manufacturing departments. The well-equipped chemical laboratories were first visited, and it was noted that a special laboratory was provided to deal with the power and fuel requirements of the factory. Specimens of raw rubber, compounding ingredients, solvents, and final products, as well as samples of rubber in process, were on view. Next the party watched the laborious process of washing crude rubber, admired the large rooms in which the washed crude is dried, and then visited the rooms in which the rubber is mixed with sulphur and other ingredients. Then followed visits to the departments in which motor tyres are vulcanised, and a fascinating inspection of the various steps necessary to make rubber shoes. The huge vulcanising autoclaves were seen in operation, disgoring a seemingly endless train of vulcanised boots. At the conclusion of the visit an excellent tea was provided for the visitors. In returning thanks for the hospitality of the company, the President, Mr. F. H. Carr, said how much the Society was indebted to the company for allowing the Edinburgh Section to benefit from the help of Mr. W. A. Williams.

Thursday ended with a reception in the City Chambers by the Lord Provost and Magistrates of the City of Edinburgh. The museum illustrating the antiquities of the City was thrown open to the inspection of members, who were greatly interested in its artistic and other treasures, which included many valuable manuscripts and specimens of historic importance.

The Walter Scott Country

After the deluges of Tuesday and Thursday the Clerk of the Weather evidently felt that he was not making his proper contribution to the success of the annual meeting, for Friday, the day fixed for the all-day excursion into Sir Walter Scott's country, turned out to be a beautiful day.

Four chais-à-bancs provided the transport, and following a start at 10.15 the city was soon left behind, and the first halt called at Soutra Hill, 1200 feet above sea level. For a few minutes we enjoyed a wonderful view of East Lothian, and then took the road again through Lauder and Earlston.

The route then led through a beautiful stretch of country becoming more wooded until Bemersyde Hill was reached, when the interest and grandeur of the view again compelled a halt.

No wonder that Scott always stopped at this point to feast his eyes on the view, and less wonder still that on his last journey round Bemersyde Hill, to his resting-place in Dryburgh Abbey, his horses drawing the hearse stopped by force of habit at their master's favourite viewpoint.

The horseshoe bend of the Tweed at our feet, backed by the wooded hills, Bemersyde nestling away to the

left, and the Triple Eildons towering like silent watchers beyond, combined to make up what must be one of the most enchanting views of the Borderland.

Dryburgh Abbey, brimful of historic interest, was our next stopping-place. Here a guide conducted us through the ruins, and gave us a complete picture of the life which centred in the abbey 760 years ago. Sir Walter Scott's tomb was pointed out to us, and there certainly could not have been a more appropriate resting place for the Wizard of the North than this spot with its stately cedars and yews.

Time would not allow of a longer stay, and the leading driver set such a pace on leaving as to suggest that he, no less than ourselves, was by this time aware of the calls of the inner man.

Melrose had been chosen for the mid-day halt, and here at the George and Abbotsford Hotel a very excellent luncheon was provided.

On leaving Melrose we had a glimpse of the abbey, and regretted that time would not permit of a closer inspection of its architectural beauties.

A passing view of Abbotsford, the monument of Scott's ambition, was all that was possible.

The beauty of the next part of our journey quite defies description. From Melrose the road follows the valley of the Tweed amid delightful scenery, and it was with a feeling of having come down to earth that we drove up to the imposing Hydro Hotel at Peebles.

Here a cup of tea was very welcome, and we were then able to enjoy for a short while the view from the terrace of the hotel.

The direct road to Edinburgh was not followed, but a digression made on the Glasgow-Biggarr road, and so home through West Linton and Penicuik. So closed a day which was remarkable no less for the excellence of the arrangements than for the pleasure it gave to the party.

Scottish Oils, Ltd.

On Friday afternoon a party travelled by road to Grangemouth to visit the refinery of Scottish Oils, Ltd. After a pleasant journey, the refinery was sighted, but for a time no obvious means of access was found. The driver eventually discovered and forced a breach which he found difficult, if practicable, and we were welcomed by Mr. A. M. Wylie, the manager, who, assisted by Mr. J. G. Annan, the chief chemist, and Messrs. R. C. Thomson and A. Patterson, engineers, conducted us round the works. All were of accord in admiring this new works, which was evidently a model of efficiency of design and operation. Economy of labour and heat were most apparent, and, indeed, so few people were in evidence on the plant that a lighthouse keeper's job seemed almost convivial in comparison. After tea Mr. W. J. A. Butterfield conveyed thanks to the Scottish Oils Company, Ltd., for their hospitality. The return journey was made via Queensferry and the Forth Bridge back to Edinburgh.

The Excursion to St. Andrews

It was unfortunate that so small a number of members was able to stay to take part in the interesting excursion to St. Andrews on Saturday, July 9.

The party left Edinburgh at 9.30 for St. Andrews.

The journey gave an opportunity of seeing something of the Forth Bridge for those who had not already made this excursion. As the party arrived at St. Andrews at 11.22, most of the members spent the remainder of the morning in visiting places of historic interest in the town. A fine view of the town and surroundings was obtained from the top of the old ruined tower of the church of St. Regulus, whilst the ruins of the old cathedral, built on the site of the old church, were very striking. Most of the members also found time to visit the old castle and to admire the views of sea and coast from its walls.

The party were welcomed at the University in the afternoon by Prof. Read, and were taken into the main lecture room, where an interesting exhibit had been arranged illustrating the nature of the research work carried out in the research laboratories. Amongst the exhibits were specimens of methyl glucosides and other derivatives used in investigating the constitution of sugars, and also interesting specimens of various varieties of eucalyptus oils and of piperitone and its derivatives.

Copies of theses presented by research students for the Ph.D. degree were shown to illustrate the way in which the work was written up.

Prof. Read gave a short account of the general nature of the research work, and explained the programme to be followed in visiting the laboratories.

The party then proceeded through the fine chemical laboratories of the college, and had an opportunity of seeing some interesting apparatus used (amongst other things a microbalance, a new form of polariscope, etc.), whilst in the research library a collection of interesting old books had been arranged. A visit was also paid to the physics laboratories under the guidance of Prof. Allen. Next the party proceeded to the college chapel, which is the oldest part of the college buildings; the visitors saw the elaborate old tomb of Bishop Kennedy, founder of St. Salvator's College, and heard an explanation of its symbolic carvings and also saw the university mace and other interesting objects. Visits were then paid to the main library of the university in another part of the town at a short distance, to the old library, the new Carnegie building, and the new science reading rooms. Passing through the Botanical Gardens to the Physiological Department, the party was shown over the laboratories by Prof. Herring. The visit ended with tea in the buildings of the Divinity College, and the party returned to Edinburgh by the 5.35 train, having greatly enjoyed a thoroughly well-planned visit.

At the conclusion of another successful Annual Meeting it is of interest to note some of the names of those who were present. The list includes the following:—

W. M. Ames, Dr. David Bain, Andrew Barclay, Alex. H. Bennett, William A. Benton, Major Robert Bruce, W. J. A. Butterfield, A. George Byard, W. A. S. Calder, Francis H. Carr, Dr. R. M. Caven, P. Coburn, Dr. R. T. Colgate, A. W. Cowan, Dr. Cox, F. P. Coyne, Dr. J. A. Cranston, C. J. T. Cronshaw, Noel P. Cross, Dr. William Cullen, G. D. Elsdon, E. V. Evans, Dr. Thomas Ewan, G. A. Findlay, C. P. Finn, G. H. Ford, G. H. Gemmell, T. S. F. Gibson, W. S. Gill, Major Vivian

F. Gloag, F. A. Greene, F. E. Hamer, J. E. G. Harris, H. C. Head, E. A. Hebden, Prof. G. G. Henderson, Prof. W. R. Hodgkinson, H. J. Hodsman, Dr. Alex. Hynd, Major William Jardine, E. Gabriel Jones, L. A. Jordan, H. A. D. Jowett, Dr. W. O. Kermack, C. A. Klein, A. W. Knapp, Dr. C. H. Lander, S. B. Langlands, Dr. A. Lander, Dr. J. P. Longstaff, Prof. H. Louis, Arthur H. Lymn, A. Douglas MacCallum, J. W. McDavid, Lieut.-Col. J. L. A. Macdonald, James MacGregor, Basil G. MacLellan, James MacLeod, A. Marsden, Dr. Percy May, Prof. A. W. C. Menzies, G. F. Merson, Dr. S. Miall, Frances M. G. Micklethwait, J. P. Miller, Emile Mond, J. W. Napier, Philip B. Nicholson, Col. G. P. Pollitt, Prof. J. Read, Dr. E. H. Rodd, F. H. Rogers, J. W. Romanes, V. Ronald, J. D. M. Ross, Prof. F. M. Rowe, A. Rudge, John Russell, Richard Seligmann, Dr. E. W. Smith, John Sutherland, Peter Tainsh, Adam Tait, H. Talbot, Edwin Thompson, Sir James Walker, J. Adam Watson, Dr. H. E. Watt, D. R. Wattleworth, W. A. Williams, W. T. H. Williamson, Hubert R. Wood.

CANADIAN NOTES

According to the financial statement of the Canadian Westinghouse Co., Ltd., this concern made substantial progress during 1926. The company earned 18.3% on the capital stock as compared with 14.3% in 1925. Operating profits are shown at \$1,796,764, from which are written off \$250,000 for depreciation of plant and property, \$140,000 for Dominion taxes for 1926, and \$40,000 transferred to pension fund. The net profits are \$1,366,741. Dividends, at the rate of 8% per annum, plus an extra dividend of 2%, will absorb \$743,290. The balance of \$623,451 is carried forward to profit and loss, and this account shows a surplus of \$4,244,933. The demand for electrical equipment for pulp and paper and hydro-electric power was responsible for the large total business.

The Selective Flotation of Canadian Ores

The Mines Branch of the Dominion Department of Mines at Ottawa has issued Memorandum No. 29, dated March, 1927, dealing with "Selective Flotation as Applied to Canadian Ores." The Memorandum is by Mr. C. S. Parsons, Engineer, Division of Ore Dressing and Metallurgy. Canada possesses many deposits of complex ores, such as lead-zinc iron sulphides, copper-zinc iron sulphides, copper iron sulphides, and other combinations of these minerals, many of which contain values in both gold and silver. The Mines Branch of the Department of Mines, through its Ore Dressing and Metallurgical Laboratories at Ottawa, has made numerous investigations into the treatment of such Canadian ores by selective flotation. The purpose of this review is to bring more directly to the attention of the mining public the information which has been acquired, and the progress which has been made in the treatment of ores by this method, and also to point out the assistance the Government is rendering the mining industry by maintaining at Ottawa fully-equipped ore dressing and metallurgical laboratories for research on the treatment of ores and metallurgical products. A brief description of the flotation equipment of these laboratories is given in order that the reader may better realise the type of work which can be performed.

CANADIAN HYDRO-ELECTRIC POWER

The Manitoba Power Co., Ltd., is extending its plant at Great Falls, Man. The extension will cost more than \$500,000.

The West Kootenay Power Co. (a subsidiary of Consolidated Mining and Smelting Co., Ltd.) has begun the construction of a third unit on the Kootenay River at South Slocan, about 13 miles south of Nelson, B.C. The plant will generate 60,000 h.p., which will be utilised to meet increased demands through extensions of the Trail smelter.

MINING RESEARCH AT BIRMINGHAM

An interesting report on recent work done at the Mining Research Laboratory of the University of Birmingham has just been issued by the Executive Board, under the signature of the Director, Dr. J. S. Haldane (President of the Institution of Mining Engineers). The members of the Board are Professor Sir John Cadman (formerly Professor of Mining at the Birmingham University); Mr. G. P. Hyslop (North Staffordshire Colliery Owners' Association); Mr. W. A. Lee and Mr. W. G. Phillips (representing the Mining Association of Great Britain); Mr. Ivon Graham (Secretary and Assistant Director of the Mining Research Laboratory); and the following, representing the Birmingham University—Professor W. N. Haworth (Chemistry), Professor K. Neville Moss (Coal Mining), and Professor A. W. Nash (Oil Mining).

The investigation of the conversion of coal into oil by hydrogenation was commenced in 1923 for the purpose of ascertaining how far the Bergius method of treatment with high-pressure hydrogen at a temperature in the neighbourhood of 400° C. could be made applicable to English coals, and in order that more information might be obtained regarding the reactions involved. A considerable amount of work had been carried out during the past year for the purpose of obtaining further information regarding the type of coal most suitable for treatment in this way, that is, the type which would give the highest oil yield. Various specimens of coal of different degree of coalification, ranging from lignite to anthracite, and including also cannel coals from different sources, had been tested in detail with very valuable results. Comparative tests had been carried out in the pressure autoclave, using nitrogen in place of hydrogen, and also by carbonisation under atmospherical pressure. These experiments (to which the investigator concerned, Mr. D. G. Skinner, had devoted a large amount of time and thought) had yielded results of great interest and importance in that they had shown that the carbonaceous material which yielded a large amount of tar and oil by carbonisation at low temperatures did not necessarily give a correspondingly higher yield by hydrogenation. A detailed investigation of the hydrogenation of two types of cannel—the true boghead or torbanite, and one typical of the material frequently found in bituminous coal seams—had shown that the yield of oil from the former was not appreciably increased by hydrogenation, whilst that from the bituminous coal cannel was very much greater than by distillation.

The successful commercial application of the Bergius process is not yet assured, and the Board believe it cannot be so until more is known about the nature and value of the products resulting from the treatment of coal with high-pressure hydrogen. The investigations they are carrying out will, they believe, in the long run prove to be of very real economical value—though possibly not in the same directions as those covered by the Bergius patents. As a result of increased financial support from the British Colliery Owners' Research Association, it has been possible to obtain additional analytical assistance, and the programme of work has been extended. A considerable amount of practical work carried out during recent months has indicated that certain types of coal are more suitable than others for treatment with high-pressure hydrogen. The question as to how far fuel in the solid state, and particularly coal, is likely to be displaced in the future by liquid fuel, whether derived from coal or obtained naturally as oil, depends, states the report, to a large extent on the relative thermal efficiencies obtainable with different varieties of heat engines and internal-combustion engines. The director has been devoting much of his attention to this subject, and has now nearly completed a book in which the current assumption that an internal-combustion engine with oil as its fuel has necessarily a higher maximum thermal efficiency than a steam engine with solid coal as fuel is examined and rejected. His conclusion is that with improved furnaces, boilers and engines, solid coal will, on account of the much lower cost of the heat derived from it, more than hold its own against oil as a fuel for engines performing heavy work and will displace oil in many cases where oil has recently come to be used extensively for producing power. The report points out that as a result of the extension of work which has taken place during the past three years, the need for further accommodation for the mining research laboratory has become pressing. It is estimated that a building giving almost treble the space for laboratory, workshop, storage, secretarial and other accommodation could be erected and equipped for £4000. This building would also include space for the Fuel Research Board's investigations. The building suggested should be approximately 60 ft. by 25 ft., and should have two floors and a flat roof for any special open-air tests which might be necessary. It is believed that various colliery owners throughout the country will be willing to contribute to a fund for a new building which might be looked upon as the coalowners' research laboratory, especially for investigations on the physiological, chemical, and physical side of mining. The researches mentioned were rendered possible, the report states, by financial support from the British Colliery Owners' Research Association, whose grant of £2500 covered the general administrative expenses of the laboratory, and of researches on hydrogenation, spontaneous combustion, and physical as well as other chemical problems connected with the mining and treatment of coal. Thanks are expressed to the Association for their recent decision to increase their grant to £3000 per annum for three years from April 1 last.

SOME PROBLEMS IN THE SYNTHETIC RESIN INDUSTRY

By D. A. SPENCER, D.I.C., Ph.D., and
H. D. MURRAY, B.A., A.I.C.

Of all newly-developed fields of industrial chemistry, the one most overburdened with haphazard and still-born patents is that of artificial resins. The reason is not far to seek, for although a large number of valuable applications of resins of the phenol-formaldehyde type became obvious soon after Baekeland's early patents, the disadvantages of the earlier resins, though to a slight extent overcome, are still present.

The term "synthetic resin" in commerce covers the condensation products of formaldehyde with phenolic and urea compounds. The former have been largely employed with fillers to produce moulded articles replacing similar goods made from ebonite and vulcanite; they have also been cast and worked to produce fancy goods of a transparent or translucent nature. The latter have recently found an application as non-inflammable substitutes for celluloid.

The difficulties which have been encountered in the commercial application of these resins may be defined as those arising from the chemical nature of the resins themselves and the physical difficulties of manufacture and finishing. In addition, the increasing number of applications of these resins has necessitated modifications of the properties possessed by the simple condensation products of phenols and aldehydes, the qualities desirable in a shellac substitute being, for example, very different from those of an imitation celluloid.

DIFFICULTIES ARISING DURING MANUFACTURE

Absolute control during manufacture has not yet been attained, with the result that comparative uniformity of the product is only secured by mixing several batches. In the removal of water during or after the preliminary condensation stage in the manufacture of phenol-formaldehyde resins, control becomes increasingly difficult, and it is often necessary to check the reaction by dilution with organic solvents when dehydration is nearing completion. As a result, it frequently happens that complete condensation is not effected. The use of an excess of one of the constituents over the quantity actually required also results in uncombined reactants being present in the finished product. Chief amongst these are water, alkali catalyst, phenol and aldehyde.

When a transparent product is aimed at, an excess of water, in addition to making the resin brittle, causes a general cloudiness. Ammonia is a very general catalyst, either free or as hexamine, as it leaves no objectionable acidity. However, some means of neutralising it is desirable as it sometimes causes blistering during the final curing. The only two methods mentioned in the literature are those of Aylesworth, who adds an acid anhydride to remove excess ammonia and water, or uses a chlorinated phenol. Free phenol is often found in commercial resins, but this is no doubt often intentional, as it increases plasticity, besides giving an antiseptic value to varnishes made therefrom.

Free formaldehyde, while resulting in a harder final product, increases fragility, and is to be avoided where

the resin is to be used for the manufacture of drinking vessels, cigarette holders, and so on, owing to the irritation to the mucous membrane which results when free aldehyde is present.

Whilst it is a relatively easy matter to make an artificial resin which is practically odourless, many firms are turning out a product which is not free from odour. A sample of resin recently examined possessed this fault to a most noticeable extent. The smell was not that typical of either phenol or formaldehyde, but rather that sickly nauseating smell obtained when acetaldehyde is warmed with caustic soda. The applications of such a product are obviously limited. In general, however, it may be said that objectionable odour is a property of certain continental resins and arises from careless manufacture or the use of unsuitable starting materials. Cresol resins are usually the worst offenders in this respect. It is claimed that odourless resins have been prepared by hydrogenation of the liquid condensation product at elevated temperatures in the presence of a suitable catalyst. Resins can also be de-odourised whilst in the liquid form by steam treatment, air blowing, etc. Failing these, the presence of objectionable semi-condensation products might be mitigated by an odourless finishing varnish.

With both phenol-formaldehyde and urea-formaldehyde resins one of the problems in the manufacture of non-filled articles has been, and still is, the production of clear permanent resins. In the actual process of manufacture, the use of pure materials and the exclusion of air produce lightly coloured resins. The use of small quantities of bleaching agents, such as hydrogen peroxide, has also been advocated. By substituting urea for phenol, resins have been prepared which, when cast in the form of sheets, are similar in appearance to ordinary glass, but have the great advantage of flexibility, and are, at first sight, decidedly preferable to glass for use as non-splintering almost unbreakable windcreens on motor-cars, covers for dials on vibrating machinery, etc.

Unfortunately, it has been found that, in practice, warping of large sheets is very liable to occur, whilst on long exposure to strong light the resins darken and turn yellow.

When phenol resins are mixed with a white filler such as gypsum or wood flour, a white opaque product is obtained which should be suitable for piano keys, billiard balls, fancy articles, etc. Here again, however, the darkening on exposure to light is a great drawback, and much research and many patents have been directed towards increasing stability to light. Suggestions include steam distillation to remove any excess phenol, ether, etc., extractions of the first condensation product to remove lencu bases, hydrogenation whilst in the liquid form, protection of free hydroxyl groups by esterification and the use of sulphur-containing salts as condensing agents have also been advocated. As the best modern products, however, still suffer from this disadvantage, it would appear that a solution of the difficulty is still to be sought.

A method of producing a white opaque product from a phenol-formaldehyde resin was discovered by the authors. When small quantities of a hydroxy acid such as citric acid are added to the liquid condensation product, this is

bleached to a pale straw-yellow colour. On setting by heat treatment this becomes opaque, and by suitably regulating the temperature an ivory white substance results. This is not light resistant, but its properties are considerably improved in this direction by the addition of a white filler.

As ultra-violet light appears to be the most effective in promoting darkening, fluorescent substances such as quinine, aesculin and phosphorescent fillers as calcium sulphide etc. were added in the hope that the incident ultra-violet light would be converted into visible, and presumably less active rays, but no improvement was noticed.

Oxidation of the surface may also assist the darkening since the colour of such resins is improved by the exclusion of air during setting and, therefore, the lacquering or varnishing of the finished article might possibly reduce the amount of colour change. In this respect it is of interest to note that the sale of bangles etc. made from synthetic resin has been somewhat restricted in the East owing to the darkening in course of time being regarded as unlucky by superstitious wearers of such ornaments.

Synthetic phenolic resins made with acid catalysts are fusible, that is to say, they are not converted into hard infusible compounds on the application of heat. Such resins have been used to mix with air-drying varnishes which retain their own characteristics. The alkali catalysed resins, soluble in acetone, have been employed as stoving varnishes which are resistant to many acids. These varnishes, however, have to be stoved at a temperature of 120° C.

It would seem that the production of a suitably catalysed, air-drying resin varnish would open up its use in many fields.

In this connexion the recent use of synthetic resins as a substitute for gums in photomechanical printing processes is of interest. A layer of resin containing bichromate salts is sensitive to light, becoming insoluble in organic solvents after exposure. If the reactions which result in this hardening are analogous to those which occur in gelatin-bichromate mixtures, the light merely accelerates a tanning process which proceeds slowly in the dark, and a resin varnish hardening at normal temperatures might, therefore, be obtained by experiments along these lines.

COLOURING RESINS

Whilst there is, generally speaking, no difficulty in dyeing artificial resins, the number of dyes which can be successfully employed is limited. The acid sulphonated members of the triphenylmethane group, and such dyes as eosin, auramine and quinoline yellow appear to be most stable in the resins, though all are somewhat bleached on setting, and many are decomposed if too high a temperature is employed. In passing, a method of colouring a resin by an inorganic salt is worth recording. Specimens of black artificial resin obtained from usual sources are of a dull colour, probably because the effect is obtained by the use of a black filler such as manganese dioxide. If, however, traces of vanadium pentoxide or ammonium vanadate are added to the unset resin and the mixture warmed, the authors found that

a colour ranging from an intense deep blue to jet black (according to the amount added) is obtained. The product is interesting in that, although the colour resembles that which would be expected by the use of a black dye, it is quite stable under conditions of heat etc. which would destroy a dye. In addition, the product has the translucent, velvety blackness typical of jet, and, for the purpose of ornament, should therefore be preferable to the opaque black product as usually obtained by fillers. Possibly other oxides might be used in the same way to obtain permanent translucent colours.

CASTING AND MOULDING

When a clear, transparent product is required the resin must be cast and the articles be made by machining from the cast blocks, since moulding of the powdered intermediate form and subsequent hardening results in

Silver-topped walking-stick with phenol-formaldehyde resin foundation, photographed after being used to drive nails into a plank and similar drastic treatment. Only superficial scratches on the silver, removable on polishing, will be noticed.

a clouded product, possibly owing to imperfect "fusion" of the particles during the final setting. The technique of casting resins is, however, in a very undeveloped stage.

Unless the mould is carefully designed and scrupulously clean, the resin sticks locally, and as the main bulk contracts on setting, splitting or distortion may result. This difficulty has been overcome to a certain extent by the use of glass moulds, which are broken to remove the set product.

Lubrication of the mould surface with a substance in which the resin is soluble, either alone, or with a hardening agent, and grease (wax, machine oil, petroleum jelly) has been advocated. The last-named are, however, liable to cause the surface of the casting to be spotted. When moulding with a filler it is usual to include the lubricant in the moulding powder, and the difficulty of sticking can be practically overcome by this

means, though certain lubricants often included (*e.g.*, stearic acid) bring troubles of their own, the chief of which is staining of the finished article. Naturally, the inclusion of such lubricants is not possible when casting a transparent product. Oiled paper, metal foil, tale dust, also reduce sticking where their application is permissible.

Some manufacturers claim that a mould lined with a heavy vitreous enamel causes little trouble, but the authors found the life of such moulds comparatively short with certain resins, and sticking occurred as before.

It is possible that the major difficulties of casting could be obviated by the use of lead moulds with or without amalgamation of their inner surfaces.

It should be noticed that, as the resins contract on curing, sharp castings of intricate designs cannot be obtained. Indeed, could some resin be found which expanded, however slightly, on setting, it would form a most valuable filler for such articles as silver-backed brushes, walking-stick tops, etc., and, owing to its resiliency, such productions would no longer suffer from the unsightly denting which readily occurs when the ordinary fragile cement or rosin filler is used. In passing, it may be noted that by depositing electrolytically a layer of silver on an ornamental head turned out of synthetic resin, the authors have prepared a quite undentable walking-stick top. By incorporating some filler which reduced shrinkage to a minimum, and using such a product to fill silver and gold ornaments, it should be possible to ensure that on cooling to normal temperatures the contraction of the metal shell was greater than that of its filler and the same end achieved.

When a transparent product is not required the article is moulded, usually under pressure and at elevated temperatures. The moulding powder consists of powdered resin in the intermediate stage, a suitable filler, and occasionally a lubricant. In moulding, staining may occur when the mould is overheated or is opened before curing is complete. This difficulty, together with blistering, flow marks, etc., is not discussed here since it can be eliminated with proper care.

Quicker setting in the mould is desirable. At present the method usually adopted is to prepare an intermediate condensation product which, whilst solid at all temperatures, is elastic when warm and will yield to pressure. In this form it is pressed into heated moulds and then converted into the intermediate but non-elastic form. This is then removed from the mould and baked, the mould being thus released earlier than if the final setting occurred therein.

The use of synthetic resin for gramophone records is a very attractive suggestion, since such records would be far less fragile than those of the usual shellac type. However, a new technique of moulding and manufacture would have to be evolved, requiring new investments of plant, and for this reason alone there seems little prospect of such records being made in bulk. Apart from this difficulty, the first attempts at making experimental synthetic resin records have been disappointing owing to the soft surface and warping. It should be possible to overcome both these defects, and as a preliminary step it would be of interest to use a core of synthetic resin made from flat sheets of the material on

to mount the usual shellac sound-bearing surface. This suggestion would not apparently require much alteration in existing technique, and would certainly remove some of the fragility of the usual record.

Although the infusible product is hard and strong it is somewhat brittle and possesses comparatively little elasticity or flexibility. Unless this latter quality is modified, artificial resins will not replace celluloid or shellac in some of their most important applications. The brittleness is reduced by the incorporation of casein, protein, or cellulose in various forms or by forming solid solutions of the resin with chlorinated hydrocarbons, free phenol, or permanently fusible resin. Rubber and various oils have also been used to increase elasticity, but as a shellac substitute artificial resin is still far from perfect on this account alone.

The uses of synthetic resin are many, and, while so much research is being directed to improving their qualities and enlarging their applications, it may be confidently assumed that their importance in industry will continue to increase for many years to come. In this article only a few of the difficulties which arise in their commercial utilisation have been touched upon, and it is apparent that where such difficulties have been solved in the past they have yielded more to chance experiment than design. Until research has solved the true nature of these resins and has given us means to control the preparation of all the substances contained in them it is improbable that the major difficulties, such as lack of uniformity, will be overcome.

We would bring this problem of resin structure to the notice of organic chemists about to take up research with the warning that it is one which has been touched upon to the continued efforts of a large number of research workers throughout the world.

EDINBURGH AND EAST OF SCOTLAND SECTION

At a joint meeting of the Edinburgh and East of Scotland Sections of the Society of Chemical Industry and the Institute of Chemistry, held on March 24, 1927, Mr J. Adam Watson in the chair, a lecture on "Fire risks in industry" was given by A. M. Cameron, B.Sc., F.I.C.

The lecturer said the literature on the subject discussed in the paper was very scanty, as technical publications dealing with particular industries rarely considered the fire hazard involved in the various processes. Yet the amount of loss to the country annually through fire was extremely large, not only from the buildings and contents destroyed, but also from loss of trade during rebuilding operations. Most fires were due to preventable causes. The fact that a particular process had been carried on without untoward happenings for many years tended to obscure the fire risk, and led to neglect of precautions against it.

T. H. Gant had attempted a classification of the causes of fires as follows:—(1) Direct ignition by flame or glowing material; (2) spontaneous heating; (3) spontaneous combustion; (4) explosions; (5) electric sparks; (6) chemical reactions; (7) pressure, friction, shock, concussion; and (8) focussed rays.

The lecturer pointed out, however, that the causes of fires were so varied that anything of the nature of a complete classification was very difficult. The importance of scrupulous attention to tidiness and cleanliness was stressed. A lighted match thrown down might fall on a heap of inflammable trade waste, and might smoulder unnoticed till after closing time, and then break out into fire. The gravity of this risk was shown by the report of the Firemaster of the City of Edinburgh for 1925, which showed that out of 262 fires on industrial premises, no fewer than 59 were ascribed to lights being thrown down, and of the four six-hour periods of the 24, that between 6 p.m. and midnight showed the greatest number of fires. Apart from this risk, inflammable waste afforded fuel for a fire however started. The

cleanliness of plant and machinery was also of the greatest importance; fires were often due to plant and machinery being coated with dirt of an inflammable nature. The necessity of cleanliness and tidiness could therefore hardly be too strongly stressed, as the want of it was perhaps the most common of all causes of fires.

Taking up the question of spontaneous combustion, the lecturer remarked that perhaps the commonest causes were (1) the heating of vegetable matter due to bacterial action and slow oxidation; (2) oxygen absorption by textiles impregnated with drying and semi-drying oils; (3) ignition of carbon in a fine state of division; and (4) storage of "incompatible" substances.

Care should be taken in the storage of vegetable matter that sufficient ventilation was given. Fibrous matter was dangerous from the large air-spaces contained relative to the weight of the fibre. This caused them to retain heat for a long time, and to assist in the oxidation of drying oils if they had been absorbed by the fibre. Sacking would take up oil from oil-containing substances, and fires had been caused thereby. Sacks were also dangerous as containers of salts such as chlorates and permanganates, as friction in handling had been known to bring about spontaneous combustion; paper-lined casks should be used.

Food that had been subjected to slow charring was a source of hazard, as the carbon produced was often pyrophoric. Half-burnt fibrous textile matter, cotton etc., was also very dangerous from the low-ignition point of the carbon so produced.

Storage was then referred to, the risk of the use of straw-packing for carboys of oxidising acids being mentioned. It was pointed out that the risk of water damage should not be lost sight of, and, if possible, foodstuffs should not be stored on floors below chemicals etc.

Static electricity as a source of hazard had come into prominence of late years. Dolezalek, in 1913, had done a good deal of work on the development of current from the flow of non-conducting, or slightly conducting, liquids through pipes. He found that benzol flowing through a copper pipe at a speed of 2 metres per second gave a potential of 2000 volts; 500 to 1000 volts was, as a rule, necessary to produce a spark. Haner had recorded a case in America where ignition of petrol vapour had taken place from static produced by the running of petrol from a road tank wagon through a rubber pipe. A not dissimilar case had aroused considerable attention a few years ago at the works of the Shell-Mex Co. A spark was supposed to have jumped from a metal dip-stick on to the edge of the filling orifice of the tank, the stick being in contact with the filling tube.

Static electricity could be developed by friction, as of belts, fabrics, etc. running over pulleys. A fire at a canvas-proofing factory due to this cause was described. Static currents were not a very common cause of fires, but such cases occurred sufficiently often to render precautions against it desirable.

Inflammable vapour escaping into the atmosphere was a very frequent source of outbreaks. Apart from the fire risk, such a thing was very wasteful, and users of

processes involving the use of inflammable liquids as solvents or otherwise should consider the installation of recovery plant to avoid this loss. No process in which inflammable liquids were allowed to evaporate into the air could be considered safe.

Fires were sometimes due to ignorance of the properties of the liquids in use. Users should check the nature of solvents supplied to them from time to time. In one fire a solvent was in use that was believed to have a high flash-point; in reality it was about -10°C . It should be borne in mind that though the vapour in a work-room or plant might be insufficient to carburet the whole of the air, yet local pockets of explosive vapour might be formed. Ignition point had an important bearing on the liability of a vapour to explode when mixed with air. Moore (J., 1917, 109) had determined the ignition point of a large number of vapours. Naylor and Wheeler (Safety in Mines Research Board, Paper No. 9) had shown that the lowest ignition point did not coincide with the theoretical perfect mixture, but fell as the mixture was enriched. This might account for the ignition of vapours from upset bottles etc. at a lower temperature than usual.

The fire hazard of inflammable dust was then considered. It was pointed out that the dust of any inflammable substance could be dangerous under some conditions. Ignition of air-dust mixtures could be brought about by hot gases and naked flames, by hot bearings, by sparks from mechanical causes, by electric sparks, including frictional and static sparks. Dust explosions from overheated bearings were by no means rare in mills grinding sugar, meals, etc. The dust tended to clog up oil-cups and ways in bearings, and it was thus very important to pay attention to such matters.

Fragments of foreign matter, such as pieces of iron, stones, etc., had sometimes been the cause of explosions in mills grinding oil-seeds. Seeds from which almost all the oil had been extracted by solvents were particularly dangerous.

Electric wiring in dusty places should be periodically examined, as dust concealed faults. Fires were sometimes caused by leakage of inflammable gases. A curious instance of hydrogen being produced by the action of red-hot iron on moisture was instanced. A casting was being made in a foundry, when the mould gave way, and the molten metal forced its way into the damp sand surrounding the mould. Hydrogen was produced and found its way through fissures in the sand to the surface, where a burning gas jet caused a sharp explosion.

Carbonic oxide was produced from faulty furnaces, when the air supply was restricted by some defect. Leakages from furnaces in such a condition were a common cause of explosion.

Some instances of fires from impurities were mentioned. Bottles of volatile liquids, if isolated were not subjected to the bright rays of the sun. Flaws in windows acted as lenses, and areas of the sun occurred in corn mills from this cause, and explosions had occurred in the protection of factories was discussed. The lecturer pointed out that factories were often found where scant attention had been given to this connexion point, even fire-buckets not being always in view.

With the many devices on the market, there was no excuse for such neglect. A brief description of the various types of first-aid extinguishers was given. These could be divided into five classes, soda-acid, carbon tetrachloride, compressed carbon dioxide, foam, and dry-powder types.

Carbon tetrachloride and foam types were the most recent introductions. The former was excellent for extinguishing flare-ups of petrol etc., but owing to the toxic gases evolved in use, care was necessary in using such extinguishers in confined spaces.

Foam type extinguishers, in which a blanket of tough bubbles of carbon dioxide was projected over the burning material, were now used to a large extent. The foam was produced by mixing solutions of sodium bicarbonate and aluminium sulphate, and of some foam-producing substance, such as extract of liquorice, and now often saponin. Foam-extinguishing installations were used on a very large scale for the protection of oil tank farms.

The most important of all fire-protecting devices was the automatic sprinkler. The first cost of such installations was undoubtedly considerable, but when once installed in a building they gave a protection that no other device could give. Fire insurance companies gave large rebates in premiums in respect of buildings so fitted, in some cases as much as 70%. An adequate supply of water was necessary, and where such was not available from the public mains, elevated tanks and pumping plant were required. Sprinkler systems could be adapted to meet very varied requirements. In localities subject to severe frosts, the dry-pipe system could be used, in which the pipes throughout the building were empty of water, but immediately filled in the event of an outbreak of fire causing a head to open. Heads of non-corrosive metal or glass were in use where required. The increased use of sprinkler-installations would go far towards reducing the present large fire loss of the country.

Various types of sprinkler heads were exhibited, including the latest "Grinnell" type manufactured by Mather & Platt, of Manchester, and the paper was illustrated by numerous lantern slides which had been kindly lent to the lecturer, showing the results of fires from various sources, and the various types of fire-protection devices and fire engines, from those in use at the Great Fire of London to those of the present day.

CALENDAR OF FORTHCOMING EVENTS

Aug. 20. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. Newcastle-upon-Tyne. Annual Meeting at 2.30 p.m.

Aug. 31. ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. 22. Annual Meeting (97th year) at Leeds.

Sept. 9. INSTITUTE OF BREWING. Research Fund Committee and General Members. Visit to hop-growing and Coopers Kent. Luncheon will be held at districts meeting. (Provisional date.) Canterbury.

Sept. 14. INSTITUTION OF SANITARY ENGINEERS. Visit to the Shipping, Engineering and Machinery Exhibition at Olympia.

CORRESPONDENCE

CHEMICAL COMBINATION AND THE CONSTITUTION OF BORON HYDRIDE

SIR,—A solution of the much discussed question concerning the constitution of boron hydride, B_2H_6 , has recently been proposed by Ullmann (Ber., 1927, 60, 610). According to Ullmann the hydride may be written $(BH_4)^- (BH_2)^+$. One boron atom acquires five electrons, thus completing an octet, and is associated with four positive hydrogen atoms. This group has, therefore, one unit negative charge. The other boron atom loses three electrons, thus attaining the configuration of the helium duplet, and is associated with two negative hydrogen atoms. This group has, therefore, one unit positive charge. According to this the hydride is a polar compound. This could perhaps be tested by measurements of the dielectric constant at different temperatures.

The proposal seems to stress unduly the intrinsic stability of the helium duplet and the neon octet, that is, the stability of these completed arrangements of electrons, inherent in their symmetry and independent of the magnitude of the charges on the nuclei. The greater firmness with which an actual helium atom holds its duplet in comparison with that with which the hydrogen atom holds its single electron is due chiefly to the greater nuclear charge of the former. Neon holds its octet more firmly than the neutral atoms of the same period hold their electrons for the same reason.

There does not appear to be sufficient evidence that the intrinsic stability of an octet is great enough to allow of the unsymmetrical molecule $(BH_4)^- (BH_2)^+$ being stable in comparison with some symmetrical arrangement.

It does not appear necessary to postulate quadrivalency for boron in order to explain how two BH_3 groups combine together to form a stable molecule. Possibly B_2H_6 may be represented by the symmetrical formula of

The dots in this formula represent, in a necessarily imperfect manner, the electrons revolving in orbits, or certain extended distributions of negative charge which, according to some interpretations of the quantum theory, constitute the electronic configuration. The hydrogen atoms share electrons with the boron atoms. They may perhaps be regarded as negative ions whose negative charge is greatly deformed in the direction of the boron nuclei. The outer hydrogen atoms each share two electrons with the adjacent boron atom. Each of the inner hydrogen atoms shares one electron with one boron atom and one with the other boron atom, but both electrons of either of these hydrogen atoms are under the attractive influence of both boron nuclei.

Such a combination of two BH_3 groups will contain less energy than that of the uncombined molecules even if the hydrogen existed as undeformed negative ions. The deformation of the latter will greatly increase

the stability of the double molecule because thereby more negative charge is drawn in between the boron nuclei.

Yours faithfully,

ANGUS F. CORE

Chemistry Department,
The University, Manchester.

P.S.—Since writing the above my attention has been directed to an article by S. Sugden in the May number of the *J.C.S.* In this, Sugden suggests for B_2H_6 the constitution

The formula represents the two boron ions B^{++} as sufficiently "electron seeking" to obtain octets by sharing with each other and with the hydrogen atoms at the expense of keeping four of the hydrogen atoms "half starved." If this is the case the arrangement will be more stable than the one proposed above.

A. F. C.

S.O.S.

SIR.—The very human character of your editorials in *CHEMISTRY AND INDUSTRY* emboldens me, with some expectation of sympathy, or at least fellow-feeling, to repeat my plea that all the paper used for the *JOURNAL*, including the Abstracts, be of the thin character employed for the *JOURNAL* proper.

If you will look along a shelf containing the *JOURNAL* from 1882 to the present time, the ever-increasing bulk of the volumes must appal you, as it does the rest of us. To what Brobdignagian proportions later volumes, including *JOURNAL*, Abstracts and Index, are to swell, one dreads to think. I have not yet had the courage to add the 1925 and 1926 volumes—the former (parcelled up in anticipation of a day of Kruschen feeling) weighs some 13 lb.—to shelves already the groaning recipients of journals from not one society alone.

Hopefully yours,

HOWARD SCENCE

Ainsdale, Southport

PERSONAL AND OTHER ITEMS

Sir John Brunner and Mr. W. J. U. Woolcock, C.B.E., have returned from Germany, where they have been taking part in the discussion between the Federation of British Industries and the corresponding German organisation, the Reichsverband.

Dr. H. H. Dale, C.B.E., F.R.S., has been appointed a member of the Advisory Board of the Trustees of the Beit Memorial Fellowships for Medical Research in the place of the late Prof. E. H. Starling.

At the annual congregation of the University of Leeds, the honorary degree of D.Sc. was conferred on Prof. A. Perkins and Mr. F. Barraclough.

Dr. E. H. Tripp has been appointed chief intelligence officer to Nitram, Ltd.

F. J. Watson, B.Sc., M.Sc., has been appointed chemist in animal nutrition to Nitram, Ltd.

Mr. W. Murray Morrison, who has been associated with the British Aluminium Company since its original formation, and who has been general manager for many years, has joined the board of that company. He has also joined the board of the North British Aluminium Company.

Mr. A. G. Loble, M.Sc., has resigned the readership in electro-chemistry in the University of Manchester on taking up a commercial appointment.

Mr. V. Bloomer, M.Sc., has been appointed demonstrator in electro-technology in the Faculty of Technology of the University of Manchester.

Amongst the appointments to Junior Beit Fellowships are the following names:—Dr. F. R. Winton, who will work on the physiology and pharmacology of urinary secretion, and will complete work in progress on the physiology of plain muscle; Mr. W. R. Wooldridge, B.Sc., will work on bacterial chemistry and immunology; Mr. W. T. J. Morgan, M.Sc., will continue the investigation of the structure of the hexose-phosphoric acids; Mr. P. Eggleton, M.Sc., will investigate the carbohydrate metabolism of contractile tissues; Mr. G. F. Marrian, M.Sc., proposes further investigation of the physiological role of vitamin B, and of the chemistry of the adrenal cortex; and Mr. A. R. Fee, B.A., will investigate the chemistry of the kidney.

We very much regret to learn that Mr. B. A. Burrell, of Leeds, who has just completed his term of office as chairman of the Yorkshire Section, died on the 10th instant. Mr. Burrell was formerly secretary of the Yorkshire Section for several years, and was an original member of the Society.

We regret to announce the death of Prof. A. Miethe, so well known for his contributions to the scientific study of photography.

The late Mr. W. C. Williams, formerly Professor of Chemistry at Sheffield University, left £56,403. Subject to certain life interests, bequests are given to the Faculty of Science at Sheffield and to the Chemical Department of Manchester University; the Chemical Society will receive £1000 for the support of its Journal and Library, and the Benevolent Fund of the Institute of Chemistry will receive £400.

Sir James Kennal, managing director of Messrs. Babcock & Wilcox, Ltd., and of other companies, left £452,726, with net personalty £138,495.

Institution of Chemical Engineers

The "Quarterly Bulletin" of the Institution announces that the programme for the forthcoming winter session is now rapidly taking shape. Although conferences extending over three days are being arranged to take place in December and March, the Institution will welcome papers of outstanding interest on chemical engineering subjects for early presentation.

For the first conference, arrangements are being made for papers to be read on refrigeration, sub-liquid combustion, refractories and the use of powdered fuel, and it is hoped to arrange for a works visit in connexion with one of the papers.

A further innovation will be introduced this year in the organisation of two public lectures. The first of these will take place on Friday, October 28, 1927, when the lecturer will be Sir William Bragg, K.B.E. It is hoped that the second lecture will be delivered early in the New Year by General Georges Patart.

The President's reception will be held during the early autumn, when members will have the first opportunity of welcoming Sir Alexander Gibb to office. Due notice will be given to members nearer the date of the reception.

Optical Society

At the meeting held on June 9, Mr. T. H. Harrison, Ph.D., B.Sc., A.Inst.P., presented a paper on "The use of photo-electric cells for the photometry of electric lamps." Mr. Harrison gave a description of apparatus and experiments designed for giving the highest accuracy and precision in the photometry of electric lamps using photo-electric cells. Although the methods adopted were not novel, yet every care had been taken to obtain the highest sensitivity in the photo-electric current measuring apparatus and to maintain the lamps at a steady accurately known voltage. It was claimed, therefore, that the results were useful in showing the maximum capabilities of photo-electric cells when used in the usual manner with a sensitive electrometer or electro-scope. The actual results were tabulated. A discussion was given of the sources of error to be expected, of the method by which they may be avoided, and of the computation of the accuracy of the results.

Papers were also presented by R. Kingslake, A.R.C.S., D.I.C., M.Sc., on "An experimental study of the best minimum wave-length for visual achromatism," and by S. K. Datta, M.Sc., A.Inst.P., on "Brewster's bands. Part II."

Professor A. G. Perkin

Prof. A. G. Perkin received the honorary degree of D.Sc. at the University of Leeds on July 4. Prof. J. W. Cobb, in presenting Prof. Perkin to the Vice-Chancellor, said "the connexion of Arthur George Perkin with this University began in the year 1881, when he became a student of the dyeing department of the Yorkshire College, and indicated the path he was to tread by producing, along with Prof. J. J. Hummel, a paper on 'Some new compounds of hematin and brazilin,' the first record of research published from the department, and the beginning of a long line of researches cumulative in usefulness and distinction. This experience had been preceded by study in London and Glasgow, and was followed by works practice at the Alizarin factory of Messrs. Hardman & Holden, of which he became manager. Returning to the Yorkshire College as Lecturer and Research Assistant in 1892, he engaged upon that systematic and continuous investigation of colouring matters which he has made his life's work, fittingly recognised by the Royal Society in electing him to the Fellowship, and afterwards acclaimed by the bestowal of the Humphrey Davy Medal.

"Extended responsibilities in teaching and administration were placed upon him when in 1916 he was appointed as Professor of Colour Chemistry and Dyeing in the University. He held for a time the Deanship of

the Faculty of Technology, and on his retirement last year was made Professor Emeritus. It is consistent with his whole career that Prof. Perkin continues to work at a bench in the laboratory which had been distinguished for so long as the scene of his labours. His record maintains a double tradition, that of his family and that of the University of Leeds, in being one of pioneering effort and achievement in the furtherance of science and of its application to the service of the community through the development of a great industry. We are proud and pleased to do him honour."

Timber Research in India

The most recent report of the Dehra Dun Forest Research Institute in India gives a good idea of the research in forest products that is being carried out at the Institute and the results so far obtained. Work is divided under several sections, such as Paper Pulp, Timber Seasoning, Timber Testing, Wood Technology, etc.

Under the Paper Pulp section the use of bamboo for the commercial manufacture of pulp has for some time been established, and the chief result of the past year's work has been the establishment of the sodium sulphate method of digestion combined with fractional treatment. With it the chemical cost of digestion and bleaching has been reduced by over 40%. As a result of this, two important projects for the manufacture of bamboo pulp in India are in process of materialising.

Under the Seasoning section, the aim is to discover the best seasoning conditions for the 70 or 80 Indian timbers which can probably be used in quantity at present. Seasoning process record guide charts are now available for many species, and during the year a process of accelerated seasoning was also carried out on fifteen more species. This work will enable railway sleepers to be manufactured from ordinary woods. Two entirely new processes of seasoning timber were tried during the year, namely (1) warm air seasoning with injection of ozone, and (2) steam and high vacuum drying. The first process proved successful with timbers containing gums and oils, but a close-grained timber split badly. The vacuum process had the reverse effect, and is expected to be of great use in connexion with sleepers that are to undergo impregnation. It is proposed to instal both plants at the Institute.

The Timber Testing section is perhaps the most important, and research thereunder is devoted to six different projects. Research under two projects serves as a reliable basis for the comparison of different species of timber, and a starting point for practically all other investigations directed towards the establishment of strength data. The principal studies during the past year related to timbers suitable for hammer-handles, picker-arms, sucker-rods, tea and rubber boxes, and tail-skids for aeroplanes.

Under the Wood Preservation section various anti-septics are kept under observation, and a large number of tests carried out to test their value under varying conditions. During the past year culture tests were made in the laboratory to determine the relative toxicity of wood tar creosote and coal tar creosote. In addition a good deal of work in connexion with the microscopic identification of timbers has been performed.

In the Wood Technology section the organisation of the various lines of research has been completed and a fairly definite programme of work has been laid out. It is still too early to report final results in most of the lines of investigation taken up, but a useful body of information has been collected, some of which is already capable of direct application.

Considerable work in regard to minor products is also in progress. Investigation into the Tuba root and the survey of the plants in Burma which yield chaumooogra oil have been undertaken.

Third Census of Production (Soap and Candle Trades)

Particulars are given below of the quantities and values of the main classes of products returned on schedules for the soap and candle trades in the years 1924 and 1907. Although the figures given in respect of 1924 relate to factories and workshops situated in Great Britain only, and those for 1907 relate to the output in the United Kingdom as a whole, the comparison is not materially affected by this circumstance.

Products	1924		1907	
	Quantity Cwt.	Selling Value £	Quantity Cwt.	Selling Value £
Glycerin:				
Crude, sold or added to stock	209,000	493,000	164,000	251,000
Distilled, do do	201,000	715,000	153,000	353,000
Total --Glycerin	410,000	1,208,000	317,000	604,000
Soap:--				
Soft	311,000	483,000	562,000	432,000
Hard:--				
Household and laundry in bars and tablets	5,047,000	12,672,000	5,657,000	6,191,000
Polishing and scouring:--				
Manufacturers'	163,000	287,000	113,000	146,000
Household	420,000	917,000		
Toilet (except shaving)	433,000	3,045,000	251,000	916,000
Shaving	14,000	212,000		
Other soaps (including soap powder)	1,301,000	3,150,000	857,000	846,000
Soap stock, produced for sale	236,000	311,000		
Total --Soap	8,825,000	21,107,000	7,440,000	8,561,000
Perfumed spirits	88,000 gall.	622,000		
Perfumery, cosmetics and toilet requisites (other than perfumed spirits and soap)		1,712,000		
Candles (including night lights)	820,000	1,871,000	946,000	1,829,000
Paraffin wax (refined)	112,000	225,000	70,000	110,000
Lubricating oils and greases	262,000	410,000		171,000
Oils, other than lubricating oils	540,000	1,301,000		241,000
Oil-seed cake and meal	590,000	226,000		
Washing and scouring materials, other than soap		598,000		23,000
Waxes (other than paraffin wax, refined and blended, and products thereof)		124,000		
Grease, tallow and stearin		388,000		387,000
All other products		801,000		289,000
Total value		30,626,000		12,218,000

As regards the manufacture of perfumed spirits and perfumery, cosmetics and toilet requisites in 1907, the firms engaged in this industry were instructed to furnish their returns on schedules for the chemical industry, and the aggregates returned on all schedules were as follows:—Perfumed spirits (111,000 gall.), £302,000, and perfumery and toilet preparations (except perfumed spirits and toilet soap), £612,000. Whilst the particulars given above in regard to the output of these products in 1924 will probably be found to cover the bulk of the trade, further amounts should be added on account of the output of firms making returns on the schedule for the chemical and other industries. The aggregates now shown should, accordingly, not be regarded as final.

The particulars given with regard to soap of all kinds and of candles are believed to cover the output of all important factories and workshops. In 1912 the quantity of soap produced in the United Kingdom was returned as 8,315,000 cwt., of which 244,000 cwt. was described as hard soap, 532,000 cwt. as soft soap, 64,000 cwt. as toilet soap, and 171,000 cwt. as polishing and scouring soap. In 1912, the output of candles totalled 1,048,000 cwt. The exports from Great Britain and Ireland in 1907 of soap, including soap stock, amounted to 1,240,000 cwt., and the net imports to 624,000 cwt. In 1924, 1,534,000 cwt. of soap manufactured in the United Kingdom was exported from Great Britain and Northern Ireland, including 172,000 cwt. to the Irish Free State and 1,362,000 cwt. to other destinations. The exports from the Irish Free State to destinations other than the United Kingdom in 1924 were negligible in amount, so that the excess of exports in 1924 over those in 1907 was 122,000 cwt., to which should be added the exports of soap stock, not separated from soap in the 1907 record, making a total increase of 308,000 cwt., or about 25%, the comparison being made for the same area, i.e., the British Isles, at both dates. The net import of soap in 1924 was 267,000 cwt., including 2000 cwt. from the Irish Free State, whilst it appears that about 16,000 cwt. of soap not of British manufacture was imported into the Irish Free State in 1924. The total import of soap and soap stock into the British Isles in 1924 was thus about 309,000 cwt., or 315,000 cwt. (50·5%) less than in 1907. From all available information it is estimated that the quantities of soap of all kinds for consumption per head of the population amounted to about 18 lb. in 1907, 17½ lb. in 1912, and 19 lb. in 1924.

The quantity of candles produced in Great Britain in 1924 was 820,000 cwt., the net import into the United Kingdom amounting to 5000 cwt. (including 2000 cwt. from the Irish Free State) and the export of British candles amounted to 171,000 cwt. (including 69,000 cwt. to the Irish Free State). The trade of the Irish Free State in candles was carried on almost exclusively with Great Britain and Northern Ireland. The amount available for consumption in Great Britain and Northern Ireland was thus 721,000 cwt., together with the amount produced in Ireland. In 1907 the production of candles in the United Kingdom was 946,000 cwt., the net import was 5000 cwt., and the export of United Kingdom products amounted to 284,000 cwt. There remained therefore in the British Isles for consumption in 1907 the balance of 667,000 cwt. A similar calculation gives the quantity available in 1912 as 787,000 cwt.

The net output of the factories and workshops engaged in these industries amounted to £11,335,000, and the net output per person was £411 in 1924 and £155 in 1907. The average number of persons employed in the soap and candle industries in 1924 was 27,599, compared with 18,718 persons in 1907. The total capacity of engines engaged in the industry in 1924 was returned as 34,468 h.p., of which nearly 31% was returned as ordinarily in reserve or idle during the year. In 1907 the equivalent figure was 16,938 h.p. The capacity of electric generators in the industry in 1924 was 18,396 kw., compared with 3837 kw. in 1907.

Third Census of Production (Ink, Gum, and Sealing Wax Trades)

Particulars are given below of the values of the outputs in 1924 and 1907 of firms whose returns were made for the ink, gum and sealing wax trades. In the figures given for 1907 are included particulars regarding small quantities produced in Ireland; those for 1924 are confined to output in Great Britain:—

	1924 Selling Value £	1907 Selling Value £
Printers' ink	1,515,000	453,000
	(266,000 cwt.)	
Printers' sundries (rollers, etc.)	163,000	34,000
Inks, other than printers' ink (i.e., writing, marking, endorser, etc., and ink powders)	406,000	231,000
Gum-mucilage, paste, etc.	226,000	50,000
Typewriter ribbons, carbons and other type-writer sundries	509,000	23,000
Sealing wax	76,000	34,000
Varnish (including litho and letterpress varnishes)	59,000	18,000
	(225,000 galls.)	
Other stationers' sundries	18,000	45,000
Other products	130,000	
Total value	3,132,000	888,000

The total value of the output in Great Britain returned for these trades in 1912 was £1,144,000. Particulars given above do not cover the whole of the output of any of the specified classes of products. The figures given in respect of varnish are supplementary to those returned for the paints, colours and varnish trades already published. The kinds of varnishes given on the above table cannot be separated from other varnishes in the returns already recorded. The quantity of printers' ink recorded on schedules for the paints, colours and varnish trades was 22,000 cwt., valued at £214,000, but separate particulars of other inks are not available. Additional returns in respect of other classes of goods specified on the above table may probably be shown in returns for the manufactured stationery and kindred trades.

The increase of over 250% in the aggregate value of the 1924 output of these products shows that, after taking account of the difference in price levels in both years, a real increase in the volume of production of the trade as a whole has taken place since 1907. In 1924 exports of printers' ink amounted to 26,700 cwt., valued at £195,000, and retained imports to 12,100 cwt., valued at £31,000, the average values per cwt. being £7 6s. 2d. in the case of exports, and £2 15s. 7d. in the case of imports. The average value at the place of production was £6 per cwt. Imports and exports were small compared with the home production, the weight of the net imports being 1 per cent., and that of the exports about 9 per cent. of that of the production. The value of writing ink and ink powder exported in 1924 was £183,000, whilst retained imports amounted to £15,000 only. The net output of the factories and work-shops covered by the foregoing statement was £1,700,000 in 1924, and the net output per person employed was, in that year, £477, compared with £289 in 1912, and £280 in 1907. The average number of persons employed during 1924 was 3567, compared with 1655 in 1907. The total capacity of engines at the factories in 1924 was 2095 h.p., of which about 24% was idle or in reserve during the year. The capacity returned in 1914, Instn. 1554 h.p., and in 1907, 2125 h.p. The average number of electric generators at factories in 1924 was 14, compared with 10 in 1914, and 7 in 1907, 39 kw.

REVIEWS

SOIL CONDITIONS AND PLANT GROWTH. By SIR E. JOHN RUSSELL, D.Sc., F.R.S. Fifth edition. Pp. viii + 516. London: Longmans, Green and Co., Ltd., 1927. Price 18s. net.

This book was established, by its first edition in 1912, as a compact reference library on soil science for the general agriculturist and as a *sine qua non* for the specialist. It is the unavoidable penalty of contributing so valuable a survey of a rapidly developing subject that new and bulkier editions are demanded of the author.

So great has been the advance in the subject since the fourth edition in 1921, and so general has been the advance in all sections of the subject, that it has been found "necessary to rewrite all except the historical portions of the book." This edition brings the account of our knowledge of the constitution of the soil, and the relation of the soil to the plant, to date, by the inclusion of the recent work on soil physics, colloidal properties, base exchange, acidity, microbiology, and plant nutrition.

It is inevitable with such a rapidly advancing subject that opinions should differ about the sequence of its presentation and the distribution of emphasis. The arrangement of the matter is doubtless a wise one for those readers whom the author has chiefly in mind, but the general agricultural student and the many who merely "consult" the book will certainly need the excellent index to guide them.

There will be some of us who will feel some regret that Sir John Russell has not given more prominence to the Russian and other recent work on soil genetics and the study of the soil profile. Even "Podsol" is not to be found in the index. The author says "it seems improbable . . . that surveying by profile would prove as helpful to ecologists and agricultural advisers in England as it is expected to prove in Continental areas," and although he adds "But it is clear that the profiles must be studied . . ." this seems like a challenge to some British workers. The soil profile is the manifestation of what is going on in the soil, and would seem to be the fundamental necessity in soil studies. It is admittedly more difficult in this land of cultivated soils to study the profile, but we are not all clear why it is less important or likely to be less useful. But however much opinions may differ as to the relative importance of profile studies, we all welcome this book as an old friend increased in stature and in knowledge. N. M. COMBER

LABORATORY EXPERIMENTS IN DAIRY CHEMISTRY. By LEROY S. PALMER, Ph.D. The Wiley Agricultural Series, edited by Dr. J. G. Lipman. Pp. xiv + 84. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1926. Price 7s. 6d.

Prof. Palmer's book is intended for students who are studying biochemistry from an agricultural standpoint. It differs from many other books on practical dairy chemistry in that it is devoted to the study of the physico-chemical characters of milk and its products. If desired, however, the course outlined could be adapted easily to include quantitative estimations, as is shown by

the inclusion of a short chapter dealing with the more common estimations.

Three chapters are devoted to the study of the properties of milk, whilst butter, rennet, cheese, and milk powder are dealt with in separate chapters. Due emphasis is given to the importance of adjusting the hydrogen-ion concentration of solutions used in many of the experiments.

A feature of the book is the detailed instructions which are given for each experiment, and, whilst these will prove of great assistance to the student, they will, none the less, be of value to the demonstrator. But, in order that the student may obtain the greatest benefit from the course of practical work, it will be necessary to supplement the experiments with theoretical notes—an observation made in a few "general instructions" given by the author at the beginning of the book.

A conscientious student, after completing such a training as outlined in this course, will be in a position to appreciate the principles of physical chemistry as applied to dairy products, and should be familiar with such instruments as the ultra-microscope, viscometer, and the hydrogen-ion apparatus, now so necessary in advanced work.

In order to stimulate interest and to prevent a mechanical performance of the exercises, questions have been inserted after many of the experiments, and a good bibliography has been systematically arranged for each chapter. Useful tables are also to be found in the appendix, and the book is well indexed. This book can be confidently recommended to both student and teacher.

D. N. McARTHUR

LABORATORY MANUAL IN GENERAL MICROBIOLOGY.

Prepared by the Laboratory of Bacteriology and Hygiene. The Wiley Technical Series for Vocational and Industrial Schools, edited by J. M. JAMESON. Third edition. Pp. xxvi+472. New York: J. Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1926. Price 17s. 6d.

As a general rule a course in biology does not find a place in the curriculum taken up by the average chemist. The result is that he approaches the subject of practical microbiology in his post student days with an inadequate equipment for the task. Mr. Giltner is aware of this difficulty, for in his preface he expresses the hope that the student will "develop powers of observation" in plodding through the exercises. In the first eighteen tasks the microbe is merely a cipher in more or less mechanical operations. It either does not appear, or, if it does appear, it is not necessary to take a direct view of it. Then he introduces the microscope, and the microbe itself assumes prominence. In the subsequent exercises in Part I various organisms are introduced, and include yeasts, moulds, bacteria, and even protozoa. We have grave doubts of the wisdom of this procedure, and consider it to be educationally unsound. It would have been better to have made an intensive study of one organism before proceeding to general exercises. In one exercise (Ex. 47. Part I) the comparison of two classes of organisms (bacteria and protozoa) is effected within the limits of one simple exercise! It cannot be done. We recommend the book to those who already

possess the fundamentals of biology, for the individual exercises are explained with a lucidity that makes us understand the reason for the popularity which has followed its publication.

In the second part of the book the author has spread his net very wide, and has framed exercises of interest to agriculturists, pharmacists and medical men, as well as to chemists. Some of the exercises dealt with in Part II, particularly those dealing with animal diseases, are far beyond the capacity of the beginner. The author is not free from his countrymen's love for elaborate technical terms. We have samples of this in pp. 152 and 153. He can hardly expect us to adopt such definitions as *coprophile* = loving barnyard manure. This seems to us to be somewhat Gilbertian.

We recommend this book to all those who are learning under guidance, and to such as desire to have at hand a manual for purposes of reference. DAVID ELLIS

A CONTRIBUTION TO THE THERMOCHEMISTRY OF ORGANIC COMPOUNDS. By Dr. ENDRE BERNER. Pp. 134. Oslo: Morten Johansens Boktrykkeri, 1926.

Dr. Berner's "Contribution to the Thermochemistry of Organic Compounds" might be supposed from internal evidence to represent a thesis from the laboratory of Professor Rüben, whose application of refractometric and dilatometric methods to the study of mutarotation is well known to English readers. Dr. Berner has discussed two applications of thermochemistry to organic compounds. In the first, following in the footsteps of Thomsen, Swientoslawski, Reinberg and Fajans, he has tried to determine the thermal value of the various linkages in organic compounds. Assuming with Fajans that the heat of dissociation of diamond is 150 kg. cal. per gram-atom, and that of hydrogen is 81.3 kg. cal. per gram-molecule, he deduces concordant values for the "absolute heats of formation" of the hydrocarbons from their atoms by postulating a value 82.0 for the C-H bond and 72.7 for the C-C bond. The former value agrees closely with the heat of dissociation of the C-H bond, whilst the latter is not far removed from Fajan's value for the heat of dissociation 75.0 of the C-C bond in diamond. For hydrocarbons containing less hydrogen he deduces the values 53.8 for each link of a triple bond and 60.8 for each link of a double bond. In rings of 2, 3, 4, 5, 6, and 7 carbon atoms the average value of each bond is 59.7, 61.9, 63.6, 71.2, 71.9, 72.6. The first number in this series is a slightly modified value for ethylene; the other members show a progressive diminution of strain as the size of the ring increases up to 5 carbon atoms, but no further increase is recorded in the 6 and 7 atom rings, or in decahydronaphthalene where the value of the bond is 72.3. These results (which are a mere recalculation of the data used by Hückel) are confirmatory of Sachse's theory of "strainless rings."

The latter part of the memoir describes the calorimetric methods used by the author, and records the values which he obtained by applying these methods to the determination of the heats of combustions of several series of isomers, namely, the methyl and ethyl esters of *d*, *dl* and *meso* tartaric acid, the ethyl esters of *dl* and *meso* dimethyl- and diphenyl-succinic acids, hydro-

benzoin and *iso*-hydrobenzoin, stilbene and *iso*-stilbene. The author's conclusion (which agrees with that reached independently by Verkade and Koops) is that "The *meso*-isomers have the greatest heats of combustion, when corrections are applied for the difference in energy between isomers in the solid state, due to the crystalline condition alone." Attention is called to the fact that the heat of solution can be used instead of the heat of fusion in correcting the heats of combustion of solid isomers.

Although the experimental results do not cover a very wide field, the memoir forms an interesting review in English of the present position of the subject.

T. M. LOWRY

ANCIENT EGYPTIAN METALLURGY. By Major H. GARLAND, O.B.E., M.C., M.Inst. Metals, and Prof. C. O. BANNISTER, M.Eng., A.R.S.M. Pp. xi + 214. London: C. Griffin & Co., Ltd., 1927. Price 12s 6d.

The valuable additions which have been made in recent years to our knowledge of the development of chemistry among the ancient civilisations have resulted largely from bibliographic and palaeographic studies and discoveries. The book under notice contains an account of researches of a type calculated to make a more direct appeal to the practical chemist, since it deals with the chemical and metallurgical examination of a large variety of ancient metal specimens. The work was undertaken by the late Major Garland, formerly Superintendent of Laboratories at the "Citadel," Cairo, whose notes and critical memoranda have been ably arranged and edited by Prof. Bannister.

A preliminary chapter on the sources of the metals concerned includes also a useful summary of Egyptian chronology, and it is followed by chapters on the bronze industry, the iron age, and the tools of ancient Egypt. A further chapter deals with the metallography of antique metals. The concluding account of the cleaning, preservation, and repair of antique metal objects will be found useful by archaeologists and collectors, especially, one may suggest, if it is read in conjunction with the reports of Dr. A. Scott's valuable investigations, conducted during recent years at the British Museum, on the cleaning and restoration of museum exhibits.

In discussing the bronze industry of ancient Egypt the author indicates a very early introduction of the "cire perdue," or waste wax process for castings, which had evidently reached a high state of development among the Egyptians some two thousand years before its introduction into Greece. The hardness of the cutting edges of the copper and bronze implements of ancient Egypt is attributed solely to the effect of cold hammering, and it is stated that Græco-Roman copper razors were finished in the same way; it is interesting that microscopical evidence does not bear out the supposition that the ancient Egyptians possessed secret processes for hardening copper and bronze. Annealing appears not to have been practised, and it is considered that there is no positive evidence of welding or brazing of copper and bronze, or of soft soldering, before late Roman times; wire drawing and metal spinning were also unknown in ancient Egypt. However, methods of working metals by hand were known to the ancient Egyptians and practised by them with great ability.

The author opposes the view, held perhaps by most archaeologists, that iron was not in common use in Egypt until about 1000 B.C. On the contrary, it is stated emphatically that metallic iron was known as early as the IVth Dynasty (2900 B.C.), seeing that copper was then being produced extensively, and that iron, in the form of hæmatite, occurred in much greater quantity than copper. Further, it is argued that in the absence of iron the only implements available for carving the diorite statues of the IVth Dynasty would have been totally unsuitable ones made of copper. It is admitted that only five iron articles dating from this period down to about 1400 B.C. have been discovered, but the paucity of such finds is attributed to the ease with which iron rusts and disintegrates in the chloridic soil of Egypt; moreover, iron was a rare and useful metal, so that worn tools were probably re-made; finally, since the metal was not used for decorative, religious, or symbolical purposes, iron articles were not placed in tombs.

The author's opinions upon various debatable matters are based largely upon evidence obtained during a study of the metallography of antique metals. This section of the book, which is illustrated by numerous photo-micrographs, is of particular interest to metallurgists, since it shows clearly the value of microscopical methods in the examination of ancient metals and alloys. From this point of view it is fortunate that the copper of ancient Egypt usually contained impurities, notably iron and arsenic. Micro-structure usually affords a trustworthy indication of the original method of manufacture of antique metal objects, since it has been established that the structural characteristics of cast, worked, or annealed specimens are permanent. No evidence was forthcoming of the occurrence at atmospheric temperatures, over periods extending to five thousands years, of annealing effects, diffusion in solid solutions, recrystallisation, or crystal growth, in metal specimens of the kind. As a result of microscopic examination it has been shown that the method of casting in moulds was used, until the period of the Roman occupation, even in making such simple objects as bronze mirrors, knives, arrow tips, chisels, and plain ring bracelets. Micro-structure is also stated to provide an unfailing criterion of the authenticity of antiques in copper, bronze, or silver: "although external corrosion patinas may be skilfully copied, no practical process can be applied to metal objects that will produce the extensive internal corrosion found in examples of genuine antique origin. It is also not improbable that, when the subject has been further studied, it will be possible to state, within reasonable limits, from the extent of the internal corrosion, the actual age of a given article."

The book is written in such terms as to appeal to the cultured layman, and it cannot fail to attract the more specialised attention of the chemist and the archaeologist. It offers a peculiar fascination to students of historical chemistry. One lays it down with the reflection that those two widely sundered branches of science, chemistry and archaeology, have met on common ground as a consequence of the scientifically controlled excavations which have been carried out during the last few years at Luxor, Giza, and elsewhere in Egypt. It is very fitting that

this striking rapprochement should have occurred in that "country of dark soil" which is reputed to have bequeathed its former name of Khem to the ancient "black art" of alchemy, and thus indirectly to the modern science of chemistry.

JOHN READ

Gmelins Handbuch der Anorganischen Chemie.

Edited by R. J. Meyer and collaborators. System number 19. *Wismut und Radioaktive Isotope*. Eighth completely new and revised edition. Pp. xxii + 229. Published by the Deutsche Chemische Gesellschaft. Berlin: Verlag Chemie, G.m.b.H., 1927. Price 33 m.

Number 19, like all the other books of this excellent series, is a most thorough compilation of chemical and physico-chemical data relative, in this instance, to the metal bismuth, its compounds, mixtures, and alloys. Brief reference is also made to the radioactive elements.

The mining, mineralogy, and metallurgical extraction of bismuth are not to any extent referred to, nor are the commercial applications of the metal dealt with at any length. Abstracts from original publications are quoted so freely in the text that the ordinary and more usual English textbook style is lacking to such an extent that the book becomes almost entirely one of reference. The number of references quoted is immense, and in fact, so far as can be ascertained, complete upon those aspects of the subject intended to be covered.

The first 104 pages deal comprehensively with the chemical, electro- and physico-chemical properties of the element bismuth itself, describing also the methods of qualitative and quantitative analysis which are regarded as standard.

A further 100 pages are taken up by classified descriptions of the compounds and alloys of bismuth with hydrogen, oxygen, nitrogen, chlorine, bromine, iodine, sulphur, selenium, tellurium, boron, carbon, silicon, phosphorus, arsenic, and antimony.

In the remaining twenty pages radium, thorium, and actinium are briefly but sufficiently discussed.

The ternary system $\text{Bi}_2\text{O}_3\text{--N}_2\text{O}_6\text{--H}_2\text{O}$, the binary systems bismuth-chlorine, bismuth-bromine, and bismuth-iodine are represented graphically, as are also the binary alloy systems bismuth-selenium, bismuth-tellurium, and bismuth-antimony. N. F. BUDGEN

MATERIE, ELEKTRIZITÄT, ENERGIE. GRUNDLAGEN UND

ERGEBNISSE DER EXPERIMENTELLEN ATOMFORSCHUNG. By Dr. W. Gerlach. Pp. xi + 291. Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe, edited by Dr. R. E. Liesegang. Part VII. 2nd edition. Dresden and Leipzig: T. Steinkopff, 1926. Price, paper 15 m., bound 16.50 m.

Dr. Gerlach's book gives a comprehensive though concise survey of the modern developments of atomic theory. The division of the subject matter into thirty chapters, dealing with more or less distinct phenomena, indicates the wide range of this survey.

Chemists will find of special interest chapters 19 to 28, which deal, among other things, with various aspects of photo-chemistry, X-ray analysis, and the characteristic frequencies in the infra-red of chemical radicals in crystals.

JOHN A. CRANSTON

PARLIAMENTARY NEWS

Safeguarding of Industries (Hydroquinone and Lactic Acid)

In reply to Major Sir Archibald Sinclair, Sir P. Cunliffe-Lister said that an exemption order regarding hydroquinone was issued by the Treasury on June 23. Preparations for the manufacture of B.P. lactic acid in this country were well advanced, and the conditions for exemption laid down in Section 10 (5) of the Finance Act, 1926, were not therefore satisfied.—July 5.

Morphia (Exports)

In a written reply to Mr. Campbell, Sir W. Joynson-Hicks stated that the amount of morphia, *i.e.*, alkaloid, salts and the morphia contained in medicinal preparations, exported to various countries in 1925 and 1926 respectively was 95,725.79 oz. and 73,288.762 oz. It was not possible to distinguish between British and foreign morphia, but it might be taken that practically the whole amount exported was of British manufacture. No export of morphia was licensed until the Board of Trade was satisfied that it was required for legitimate purposes.—July 6.

Exports of Vegetable Oils to Portugal

Sir P. Cunliffe-Lister informed Mr. Lunley that the exports of edible vegetable oils refined in the United Kingdom and consigned to Portugal amounted in 1924 to 53 tons, valued at £2750; in 1925 to 63 tons, valued at £3006; and in 1926 to 1007 tons, valued at £41,757.—July 7.

Imports of Motor Spirit

In reply to Lieut.-Colonel Howard-Bury, Sir P. Cunliffe-Lister said that 101 million gals. of motor spirit were imported into Great Britain and Ireland in 1913, of which 14.9 million gals. were consigned from Russia. In 1926, 562 million gals. were imported into Great Britain and Northern Ireland, of which 55.2 million gals. were consigned from the Union of Socialist Soviet Republics.—July 7.

COMPANY NEWS

NOBEL INDUSTRIES, LTD.

The report covering the year to December 31, 1926, shows a profit of £1,469,141, compared with £1,091,920 for the previous year. Debenture interest absorbs £70,389, and after again writing off one-thirtieth of debenture issue expenses, absorbing £2977, there is available, with £230,527 brought in, £1,626,302. Last year the reserve was raised to £1,000,000, with an allocation of £450,000; no transfer to that fund is now proposed, but the dividend on the ordinary capital is increased from 10% to 15%, whilst the deferred shares receive 10% against 5%, leaving £233,390 to be carried forward. The directors state that, although the home trade, more particularly in explosives, was materially affected by the prolonged stoppage in the coal industry, the decrease in revenue thus occasioned has been more than made up by the results achieved from the activities of the constituent and associate companies in other directions and by further improvement in investment income.

MOND NICKEL CO., LTD.

The thirteenth annual general meeting was held on July 8, the Rt. Hon. Sir Alfred Mond, Bt., M.P. (chairman) presiding. Reference was made to the loss sustained through the death of the Rt. Hon. Sir Ellis Griffith, who had been a director of the company for a large number of years. After reviewing the accounts (cf. *CHEM. AND IND.*, July 8, 1927, p. 620), the chairman said that in view of the general strike and the coal strike during the past year, he thought the shareholders could congratulate themselves on the fact that the financial results of the year had been maintained on such a satisfactory level. During last autumn, accompanied by the deputy-chairman and Mr. Robert Mond, the chairman visited the company's mines and smelter in Canada, and found everything working very smoothly and efficiently. A highly-trained technical staff was in charge of every one of the operating departments, and it was gratifying to observe the very marked technical advance which had been achieved, particularly in recent years, in the treatment of the Sudbury ores. The cost of matte was one of the main factors in the cost of their finished products, and it was, therefore, a cause of satisfaction that the cost of matte had now reached a figure well below any previous record, even before the war. This was a striking advance, considering that wages were nearly double pre-war rates, and that the cost of supplies had advanced by probably 66%. A visit was also paid to the various mines of the company. At the present time the company had a larger tonnage of ore in reserve than it has had at any previous period in its history. It was estimated that at the present rate of production it had from 40 to 45 years' proved ore which it could take out. This was largely due to the satisfactory results of deeper drilling at the Frood mine, where large reserves of high-grade ore have been located. Their competitors and neighbours had discovered a high-grade copper ore at a depth of 3000 ft., and as the mines adjoined, it was exceedingly likely that similar ore would be found in the company's mine. Omitting the bad effect of the coal strike, the year's operations at Clydach were satisfactory. Further improvements were being made which had resulted in economy in fuel, greater output, reduction in repairs and greater efficiency, thus reducing the cost of the final products. A visit was next made to the subsidiary company, the American Company, at Clearfield, Pennsylvania. It had been decided to change the name to "The American Mond Nickel Company," and Mr. Shipley, a well-known engineer and man of business in America, had assumed the chairmanship of the board of the company. Mr. Barclay, their chief technical expert in these matters in England, had been sent over to assist on the technical side, and it was anticipated that this business would become in time a very remunerative and important part of the company's operations. There was a greatly increasing use in America of rolled and milled goods in nickel, nickel-copper, and other nickel alloys, and the company was extending its operations in this direction. The subsidiary company in Birmingham, Messrs. Henry Wiggin & Co., had made, in spite of the coal strike, a reasonably substantial profit. Dealing with the question of

sales and deliveries of the main products of the company, the chairman said that they were large manufacturers of copper sulphate, and in spite of strong competition from the local makers in the consuming countries, they had always been able to place all that they produced. Last year, owing to their production being less than usual, as a result of the stoppage, they were somewhat short of supply. Prices, however, were considerably better than in the year before. As regards nickel, the outlook was more promising than it has been at any other time. Deliveries during the last year exceeded those of any previous year. The work of the research and development department had become increasingly essential. There was no doubt that nickel would form an essential constituent of almost every alloy which would meet the demands of designers of machinery who were looking out for additional alloys which would have the strength, combined with corrosion-resisting properties, necessary to meet the ever-insistent demands for greater speeds, higher temperatures, and increased pressures. In order to keep in touch with developments of this kind, and ascertain exactly how these alloys should be used, it was necessary to determine the main qualities of the existing alloys and the means by which they could be improved, and the research and development department was proceeding on a line of far-reaching investigation which, in the course of time, could become more and more valuable to the company. They had also been developing nickel-copper alloys, one of which, made by Messrs. Henry Wiggin & Co., was called "Silveroid," and contains 45% of nickel. Experiments were also being made with copper-nickel alloy tubes, as against brass tubes, which it was hoped would prove successful. The company was in a fortunate position with regard to the platinum metals, as they occur with the nickel-copper in the ores, and were recovered at the end of the extraction process automatically. A final dividend of 1s. 6d. per share was declared on the ordinary shares, making 12½% for the year. The retiring directors, the Rt. Hon. Sir Alfred Mond, Bart., M.P., Viscount Erleigh, Sir Robert A. Hadfield, Bart., and Mr. Robert Mathias, were re-elected.

UNITED PREMIUM OIL AND CAKE CO., LTD.

The eighth ordinary general meeting, held on July 8, was presided over by the chairman, Mr. H. Guedalla. The net profit for the year 1926 was £54,142 (£61,468 for 1925), and with £27,170 transferred from reserves to meet the preference dividend, there was an available sum of £81,312. Interest on debenture stock absorbed £21,751; Uruguay proposition written off, £3230; provision in respect of trading losses of subsidiary companies, £23,940; leaving £32,390, plus £3452 brought in. The preference dividend absorbed £34,431, leaving £1412 to be carried forward. The effect of the coal strike was to increase considerably working costs and to cause a material diminution in both the output and the revenue, the extra cost of fuel alone for the last six months of the year under review greatly exceeding the reduction in revenue as compared with the previous year. Foreign competition was also keener than ever. Taking the chief raw material in which the company dealt, the Board of Trade returns for 1926 showed there

was a reduction in imports of 20% compared with 1924, and that of their finished products, oil imported in 1926 showed an increase of 96% compared with 1924, and cake imported showed an increase of 45%. These percentages reflected very large values, and, although the increase last year may have been somewhat abnormal, the chief cause was the selling by foreign firms which have the advantage of protection in their own country. If the mills in this country had been able to manufacture these imported products there would, with their own internal competition, have been no necessity for increased selling prices, as the increased turnover would naturally reduce the cost of manufacture. Mr. Till, who has been associated with the Premier Oil Extracting Mills for many years, resigned his position as chairman and managing director of that company on December 31 last. As from January 1 of this year the services were secured of Mr. W. E. Waterhouse as general manager, in which capacity he assumed the responsibility of the management of all the subsidiary companies, with the exception of Seatons, in Hull. Since the commencement of the current year the earnings show a considerable improvement.

MIDLAND BANK, LTD.

An interim dividend has been announced for the half-year ended June 30 last at the rate of 18% per annum, less income tax, payable on July 15.

CELANESE CORPORATION OF AMERICA

A dividend of 7% has been declared, thus clearing all arrears on the preferred stock. The total dividends paid and declared on this stock now amount to 24½%.

BRYANT AND MAY, LTD.

The directors have issued a circular setting forth conditions on which an identification of interests with the Swedish Match Company is to be set up. The business of the two companies are to be unified throughout the British Empire, other than in Asia. A new company is to be formed called The Imperial Match Company, with a capital of £6,000,000 in £1 shares divided as follows: 4,189,548 to be offered to Bryant & May ordinary shareholders in exchange on the basis of 3½ new £1 shares for each £1 share held; 1,800,000 to the Swedish Match Company; 10,452 to be subscribed in cash at par by Bryant & May. The new concern will be a holding company, and Bryant & May and J. John Masters & Co., of Barking, Essex (the latter company being controlled by the Swedish Match Co.), will continue as at present, and each company will preserve its identity. The board of the new company will consist of the following:—*Bryant & May directors*—Mr. G. W. Paton (chairman and managing director), who will be chairman of the new company; Messrs. C. E. Bartholomew (deputy-chairman of Bryant & May), W. A. Fairburn, A. Hacking, A. Hepburn, C. O. Rennie, Sir Arthur Stanley, and the Rt. Hon. John W. Wilson. *Swedish Match directors*—Mr. I. Kreuger (managing director, Swedish Match Co.); Major J. W. Hills, M.P., who is also chairman of J. J. Masters & Co. *J. John Masters & Co.*—Mr. O. I. Andren and Mr. H. O. Agrell, in addition to Major J. W. Hills.

MINERALS SEPARATION, LTD.

The twenty-second annual ordinary general meeting was held on June 30. Sir Ernest M. Clarke presided in the absence of the chairman, Mr. Francis Gibbs, owing to ill-health. The coal side of the company's business in this country and in France had been disappointing, and there were no prospects of any improvement in the near future. The ovoid plant at Aberaman, owned jointly by the Powell Duffryn Steam Coal Co. and the company, was now completed, but owing to the general depression in the coal industry it had not been possible as yet to market its products. In Spain the production of coal cleaned by the company's processes had again increased, being 249,589 tons in 1926, against 227,542 tons in 1925. After reviewing activities in the Belgian Congo and Rhodesia, the chairman stated that the development work carried out to date in Southern Rhodesia by the Southern Rhodesia Base Metals Corporation on their Copper Queen and Copper King properties confirms the opinion of their importance. Large bodies of ore-carrying copper, lead and zinc of commercial grade had already been indicated, and the development programme would be accelerated during the present dry season. The company had recently participated in an option over a new process for the recovery of tin. Experiments in the laboratory and also on a larger scale in Cornwall had been very encouraging, but it was too early to say anything definite just yet.

"SANITAS" TRUST, LTD.

The first ordinary general meeting was held on June 21, Mr. N. F. Kingzett, chairman, presiding. The report, covering the period from March 11, 1926, to May 31, 1927, shows a net profit of £62,293. After providing for the fixed dividend of 10 per cent. on the preference shares, and writing off £12,600 from underwriting commission (reducing it to £7000), the balance of £684 was carried forward. The combined profits of the constituent companies for the year to March 31, 1927, amounted to £83,031. During the year the constituent companies had made considerable progress in consolidating production and distribution of their products, which, in future years, should result in substantial reduction in costs.

AMALGAMATED PHOTOGRAPHIC MANUFACTURERS, LTD.

The sixth annual general meeting was held on June 10, Mr. F. G. Thomas (chairman) presiding. The net trading profit for 1926 was £37,100, compared with £36,048 for 1925. After providing for interest and reserve for depreciation, the net profit was £21,343, against £20,977. The year's dividend on the 8% "A" preference shares absorbed £7836, leaving, with £20,977 brought in, £34,484, which was carried forward. The improvement in the profits, which they were entitled to expect for 1926 owing to the economies in manufacture and distribution, to which reference was made at the last annual meeting, was not realised owing to the decrease in the sales brought about by the strikes. The demand, especially from the export markets, for the photographic plates manufactured at the company's Southgate factory had so far exceeded its capacity that the manu-

factory of self-toning paper had been transferred to the factory at Watford, and additional plant had been installed at the Southgate factory, increasing its capacity for the manufacture of plates by over 50%. The demand for the projectors manufactured by the company had exceeded the capacity of the Kershaw factory at Leeds, and an extension to the factory had been made in order to increase the output. With regard to the current year, for the first five months the sales in each month showed an improvement over the corresponding figures for last year amounting to about 15%.

CAPE ASBESTOS CO., LTD.

The thirty-fourth ordinary general meeting was held on June 24, Mr. L. Breitmeyer, chairman, presiding. The net profit for 1926, after providing for taxation and bad and doubtful debts, and including income from the Turin branch, amounted to £36,766, an increase of £10,281 over the previous year. With the sum of £10,491 brought forward from 1925, there was an available profit of £47,257, from which was deducted the 5% preference dividend amounting to £3600, an addition to the reserve fund of £15,000, and £2500 to the staff benefit fund, leaving available £26,157. A dividend was declared of 10% on the ordinary and preference shares, absorbing £15,500, leaving £11,757 to be carried forward. There was an increasing demand for blue asbestos, and the new amosite property had also contributed to the year's results. Encouraged by the satisfactory introduction of amosite, the further opening up of the mines would be taken in hand. Plant and equipment would require a considerable expenditure, and to meet this and also to provide for the expansion of their general business, it was intended at some future date to offer the remaining unissued £20,000 ordinary and preference shares to shareholders and to propose an increase of the share capital. There was again a record turnover at the Turin factory, the gross volume of trade showing an increase of nearly 30%.

LAGUNAS NITRATE CO., LTD.

The thirtieth annual general meeting was held on July 7, Mr. R. E. Morris, chairman, presiding. A trading profit was made for 1926 of £14,327, increased to £17,473 by the receipt of interest and transfer fees, but after meeting the heavy expenses entailed by the shutting down of the oficina, the necessary administration expenses and income tax, there was a loss of £11,939. The extraction of caliche was continued until December last, but this work has now been stopped as, in view of the Chilean Government's declaration that the present duty on nitrate would be maintained until June, 1928, it will probably be impossible to resume manufacture this year. It was essential that the Chilean Government should render assistance to the industry. It was estimated that if nitrate of soda could be sold to the agriculturists at about £10 10s. per ton, a consumption of from 2,000,000 to 2,250,000 tons might be anticipated during the current nitrate year. For the year just closed the consumption was only 1,753,000 tons, compared with 2,092,000 tons for the previous year.

WELSBACH LIGHT CO., LTD.

A dividend has been recommended of 5%, less tax, being the same as for the three preceding years.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acid Acetic, 40% tech.—£19 per ton.
 Acid Boric, Commercial.—Cryst., £34 per ton; Powder, £36 per ton.
 Acid Hydrochloric.—3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
 Acid Nitric 80° Tw.—£21 10s.—£27 per ton makers' works, according to district and quality.
 Acid Sulphuric.—Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 60s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
 Ammonia Alkali.—£6 15s. per ton, f.o.r. Special terms for contracts.
 Bisulphite of Lime.—£7 10s. per ton, packages extra.
 Bleaching Powder.—Spot, £9 10s. per ton d/d.; Contract, £8 10s. per ton d/d., 4-ton lots.
 Borax, Commercial.—Crystals, £19 10s.—£20 per ton; Granulated, £19 per ton; Powder, £21 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
 Calcium Chloride, Solid.—£5—£5 5s. per ton, carr. paid.
 Copper Sulphate.—£25—£25 10s. per ton.
 Methylated Spirit, 61 O.P.—Industrial, 2s. 5d.—2s. 10d. per gal.; Pyridinised Industrial, 2s. 7d.—3s. per gal.; Mineralised, 3s. 6d.—3s. 10d. per gal.; 64 O.P. 1d. extra in all cases. Prices according to quantity.
 Nickel Sulphate.—£38 per ton d/d.
 Nickel Ammon. Sulphate.—£38 per ton d/d.
 Potash, Caustic.—£30—£33 per ton. Potass. Bichromate.—4½d. per lb. Potass. Chlorate.—3½d. per lb. ex whf. Lond. in cwt. kegs.
 Salammoniac.—£45—£50 per ton. Chloride of Ammonia.—£37—£45 per ton, carr. paid.
 Salt Cake.—£3 15s.—£4 per ton d/d. bulk.
 Soda, Caustic, solid.—Spot lots; delivered in 4-ton lots. £15 2s. 6d.—£18 per ton, according to strength. 20s. less for contracts.
 Soda Crystals.—£5—£5 5s. per ton ex railway depots or ports.
 Sod. Acetate 97/98%.—£21 per ton. Sod. Bicarbonate (refined).—£10 10s. per ton, carr. paid. Sod. Bichromate.—3½d. per lb. Sod. Bisulphite Powder 60/62%.—£17 10s. per ton, home market, 1-cwt. iron drums included. Sod. Chlorate, 2½d. per lb.
 Sod. Phosphate.—£14 per ton, f.o.r. London, casks free.
 Sod. Sulphate (Glauber's Salt).—£3 12s. 6d. per ton.
 Sod. Sulphide conc. solid 60/65.—Spot £13 5s. per ton, contracts £13 carr. paid. Sod. Sulphide "cryst."—Spot £8 12s. 6d. per ton, contracts £8 10s. carr. paid. Sod. Sulphite, Pea Cryst.—£14 per ton, f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony Sulphide.—Golden.—6½d.—1s. 5½d. per lb. according to quality. Crimson.—1s. 4d.—1s. 6d. per lb., according to quality.
 Arsenic Sulphide, Yellow.—1s. 9d. per lb.
 Barytes.—£3 10s.—£6 15s. per ton, according to quality.
 Cadmium Sulphide.—2s. 6d.—2s. 9d. per lb.
 Carbon Bisulphide.—£20—£25 per ton, according to quantity.
 Carbon Black.—5½d. per lb., ex wharf.
 Carbon Tetrachloride.—£45—£50 per ton, according to quantity, drums extra.
 Chromium Oxide, Green.—1s. 1d. per lb.
 Diphenylguanidine.—3s. 9d. per lb.
 Indiarubber Substitutes, White and Dark.—5½d.—6½d. per lb.

Lamp Black.—£35 per ton, barrels free.
 Lead Hyposulphite.—8d. per lb.
 Lithopone, 30%.—£22 10s. per ton.
 Mineral Rubber "Rubpron".—£13 12s. 6d. per ton, f.o.r. London.
 Sulphur.—£9—£11 per ton, according to quantity. Sulphur Precip. B.P.—£47 10s.—£50 per ton, according to quantity.
 Sulphur Chloride.—4d.—7d. per lb., carboys extra.
 Thiocarbamide.—2s. 6d.—2s. 9d. per lb., carriage paid.
 Thiocarbamilide.—2s. 1d.—2s. 3d. per lb., according to quantity.
 Vermilion, pale or deep.—6s.—8s. 3d. per lb.
 Zinc Sulphide.—1s. per lb.

WOOD DISTILLATION PRODUCTS

Acetate of Lime.—Brown, £8 10s.—£9 5s. per ton. Grey, £15 10s. per ton. Liquor, 9d. per gal. 32° Tw.
 Charcoal.—£6 15s.—£10 per ton, according to grade and locality.
 Iron Liquor.—1s. 3d. per gal. 32° Tw.; 1s. per gal. 24° Tw.
 Red Liquor.—9d.—10d. 16° Tw. per gal.
 Wood Creosote.—1s. 9d. per gal., unrefined.
 Wood Naphtha.—Miscible, 3s. 9d.—4s. per gal., 60% O.P. Solvent, 3s. 11d.—4s. 3d. per gal., 40% O.P.
 Wood Tar.—£4—£5 10s. per ton and upwards, according to grade.
 Brown Sugar of Lead.—£40 15s.—£41 10s. per ton.

TAR PRODUCTS

Acid Carbohc.—Crystals, 8d.—9d. per lb. Crude 60's, 2s. 4d.—2s. 8d. per gal.
 Acid Cresylic, 99/100.—2s. 8d.—2s. 9d. per gal. 97/99.—2s. 1½d.—2s. 4½d. per gal. Pale, 95%, 2s.—2s. 3d. per gal. Dark, 1s. 9d.—2s. 1d. per gal.
 Anthracene Paste.—A quality, 2½d.—3d. per unit, 40%—3d. per unit; Anthracene Oil.—Strained, 8d.—8½d. per gal. Unstrained, 7½d.—8d. per gal. Both according to gravity.
 Benzole.—Crude 65's, 11d.—1s. per gal., ex works in tank wagons; Standard motor, 1s. 9d.—2s. 2d. per gal., ex works in tank wagons; Pure, 1s. 7d.—2s. 3d. per gal., ex works in tank wagons.
 Toluole.—90%, 1s. 8d.—1s. 10½d. per gal. Pure, 2s.—2s. 3½d. per gal.
 Xylol.—2s.—2s. 4d. per gal. Pure, 2s. 6d. per gal.
 Creosote.—Cresylic 20/24%, 10½d. per gal. Standard specification, 6½d.—8½d. per gal. Middle Oil, 7½d.—7½d. per gal. Heavy, 8½d.—8½d. per gal. Salty, 7d. per gal., less 1½%.
 Naphtha.—Crude, 7½d.—8d. per gal., according to quality. Solvent 90/160, 1s. 2d.—1s. 6d. per gal. Solvent 95/160, 1s. 5d.—1s. 6d. per gal. Solvent 90/190, 11d.—1s. 4d. per gal.
 Naphthalene Crude.—Drained Creosote Salts, £7 10s. per ton. Whizzed or hot pressed, £8 10s.—£9 per ton.
 Naphthalene.—Crystals, £11 10s.—£13 10s. per ton. Flaked, £12 10s.—£13 per ton.
 Pitch, medium soft.—82s. 6d.—85s. per ton, f.o.b. according to district. Nominal.
 Pyridine.—90/140.—7s. 6d.—13s. per gal. Nominal. 90/180.—4s. 6d.—5s. per gal. Heavy.—5s.—8s. per gal.

INTERMEDIATES AND DYES

In the following list of Intermediates delivered prices include packages except where otherwise stated.
 Acid Gamma.—4s. 9d. per lb.
 Acid Amidonaphthol disulpho (1.8.2.4.)—10s. 9d. per lb.
 Acid H.—3s. 3d. per lb. 100% basis d/d.
 Acid Naphthionic.—1s. 6d. per lb. 100% basis d/d.
 Acid Neville and Winther.—4s. 9d. per lb. 100% basis d/d.
 Acid Sulphanilic.—9d. per lb. 100% basis d/d.
 Aniline Oil.—7½d. per lb., naked at works.
 Aniline Salts.—7½d. per lb., naked at works.

Anthranilic Acid.—6s. per lb. 100%.
 Benzaldehyde.—2s. 3d. per lb.
 Benzidine Base.—3s. 3d. per lb. 100% basis d/d.
 Benzoic Acid.—1s. 8½d. per lb.
 o-Cresol 29/31° C.—4½d. per lb.
 m-Cresol 98/100%.—3s. per lb.
 p-Cresol 32/34° C.—2s. 8½d. per lb.
 Dichloraniline.—2s. 3d. per lb.
 Dimethylaniline.—1s. 11d. per lb. d/d. Drums extra.
 Dinitrobenzene.—9d. per lb., naked at works. £75 per ton.
 Dinitrochlorbenzene.—£84 per ton d/d.
 Dinitrotoluene.—48/50° C.—8d. per lb., naked at works.
 Dinitrotoluene.—66/68° C.—9d. per lb., naked at works.
 Diphenylamine.—2s. 10d. per lb. d/d.
 α-Naphthol.—2s. per lb. d/d.
 β-Naphthol.—11d.—1s. per lb. d/d.
 α-Naphthylamine.—1s. 3d. per lb. d/d.
 β-Naphthylamine.—3s. per lb. d/d.
 p-Nitraniline.—1s. 9d. per lb. d/d.
 m-Nitraniline.—3s. per lb. d/d.
 o-Nitraniline.—5s. 9d. per lb.
 Nitrobenzene.—6d. per lb., naked at works.
 Nitronaphthalene.—1s. 3d. per lb. d/d.
 R. Salt.—2s. 2d. per lb. 100% basis d/d.
 Sodium Naphthionate.—1s. 8½d. per lb. 100% basis d/d.
 o-Toluidine.—7½d. per lb., naked at works.
 p-Toluidine.—2s. 2d. per lb., ex works, naked.
 m-Xylidine Acetate.—2s. 6d. per lb. 100%.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic, Pure, 80%.—£39 per ton, ex wharf London, in glass containers.
 Acid, Acetyl Salicylic.—2s. 5d.—2s. 6d. per lb.
 Acid, Benzoic B.P.—2s.—2s. 3d. per lb. for synthetic product, according to quantity. Solely ex Gum—1s.—1s. 3d. per oz., according to quantity.
 Acid, Boric B.P.—5 cwt. lots. Cryst. 41s. per cwt. Powder 45s. per cwt. Carriage paid any station in Great Britain in ton lots.
 Acid, Camphoric.—19s.—21s. per lb.
 Acid, Citric.—1s. 7½d.—1s. 10d. per lb. Less 5%.
 Acid, Gallic.—2s. 8d. per lb. for pure crystal in cwt. lots.
 Acid, Pyrogallie, Cryst.—7s. 3d. per lb. Resublimed.—8s. 3d. per lb.
 Acid, Salicylic.—B.P. pulv. 1s. 3½d.—1s. 6d. per lb. Technical 11½d.—1s. per lb.
 Acid, Tannic B.P.—2s. 8d.—2s. 10d. per lb.
 Acid, Tartaric.—1s. 3½d. per lb. Less 5%.
 Amidol.—9s. per lb. d/d.
 Acetanilide.—1s. 6d.—1s. 8d. per lb. for quantity.
 Amidopyrin.—8s. 6d. per lb.
 Ammon. Benzoate.—3s. 3d.—3s. 9d. per lb., according to quantity.
 Ammon. Carbonate B.P.—Lump £37 per ton, Powder £30 per ton, in 5-cwt. casks. Resublimed.—1s. per lb.
 Atropine Sulphate.—11s. per oz. for English make.
 Barbitone.—6s. per lb.
 Benzonaphthol.—3s. 3d. per lb.
 Bismuth Carbonate.—9s. 9d.—10s. per lb. Bismuth Citrate.—9s. 6d.—9s. 9d. per lb. Bismuth Salicylate.—8s. 9d.—9s. per lb. Bismuth Subnitrate.—7s. 9d.—8s. per lb. Bismuth Nitrate.—5s. 9d.—6s. per lb. Bismuth Oxide.—13s. 9d.—14s. per lb. Bismuth Subchloride.—11s. 9d.—12s. per lb. Bismuth Subgallate.—7s. 9d.—8s. per lb. Extra and reduced prices for smaller and larger quantities respectively; Liquor Bismuthi B.P. in W. Qts.—1s. 1d. per lb.; 12 W. Qts.—1s. per lb.; 36 W. Qts.—11½d. per lb.
 Borax B.P.—5 cwt. lots. Crystal 25s. per cwt. Powder 27s. per cwt., according to quantity, carr. paid any station in Great Britain in ton lots.

Bromides.—Ammonium.—2s. 4d. per lb. Potassium.—1s. 11d. per lb. Sodium.—2s. 2d. per lb. All spot.

Calcium Lactate.—1s. 3½d. per lb.

Chloral Hydrate.—3s. 6d. per lb., duty paid.

Chloroform.—2s. 3d.—2s. 7½d. per lb., according to quantity.

Cresote Carbonate. 6s. per lb.

Ethers: Prices for Winchester quarts; dozen Winchester quarts; carboys or drums; and 10 cwt. lots respectively; 730.—1s. 2½d.; 1s. 2d.; 1s. 1½d.; 1s. 0½d.; 720 tech.—1s. 5½d.; 1s. 5d.; 1s. 4½d.; 1s. 3½d.; 720 pur. (Aether P.B. 1914)—2s. 4d.; 2s. 3½d.; 2s. 3d.; 2s. 2d.

Formaldehyde.—£39 per ton. Ex wharf in barrels.

Guaiaecol Carbonate.—5s. per lb.

Hexamine.—2s. 4d.—2s. 6d. per lb.

Homatropine Hydrobromide.—30s. per oz.

Hydrastine Hydrochlor.—English make offered, 120s. per oz.

Hydrogen Peroxide (12 vols.).—1s. 4d. per gal. f.o.r. makers' works, naked. B.P.—1 lb., 16s. per doz.; ½ lb., 9s. 6d. per doz.; ¼ lb., 6s. 6d. per doz.

Hydroquinone.—2s. 11d. per lb.

Hypophosphites.—Calcium 3s. 6d. per lb. for 28-lb. lots. Potassium 4s. 1d. per lb. Sodium 4s. per lb.

Iron Ammon. Citrate B.P.—2s. 1d.—2s. 4d. per lb. Green, 2s. 4d.—2s. 9d. per lb. U.S.P. 2s. 2d.—2s. 5d. per lb.

Iron Perchloride.—4d. per lb., 22s. per cwt.

Magnesium Carbonate.—Light Commercial £31 per ton net.

Magnesium Oxide.—Light Commercial £62 10s. per ton, less 2½%; Heavy Commercial £21 per ton, less 2½%; in quantity lower; Heavy Pure 2s.—2s. 3d. per lb.

Menthol.—A.B.R. recryst., B.P., 18s. 6d. per lb. net. Synthetic detached crystals, 11s.—14s. 6d. per lb., according to quantity; Liquid (95%), 12s. per lb.

Mercurials, B.P.—Up to 1 cwt. lots—Red oxide, 7s. 6d.—7s. 7d. per lb., Levig, 7s.—7s. 1d. per lb.; Corrosive sublimate, Lump, 5s. 9d.—5s. 10d. per lb., Powder, 5s. 2d.—5s. 3d. per lb.; White precip., Lump, 5s. 11d.—6s. per lb., Powder, 6s.—6s. 1d. per lb., extra fine, 6s. 1d.—6s. 2d. per lb.; Calomel, 6s. 4d.—6s. 5d. per lb.; Yellow Oxide, 6s. 10d.—6s. 11d. per lb.; Persulph B.P.C., 6s. 1d.—6s. 2d. per lb.; Sulph. nig., 5s. 10d.—5s. 11d. per lb. Special prices for larger quantities.

Methyl Salicylate.—1s. 9d. per lb.

Methyl Sulphonal.—9s. 6d.—9s. 9d. per lb.

Metol.—11s. per lb. British make.

Paraformaldehyde.—1s. 9d. per lb. 100% pdr.

Paraldehyde.—1s. 4d. per lb.

Phenacetin.—2s. 9d.—3s. per lb.

Phenazone.—4s. 3d.—4s. 6d. per lb.

Phenolphthalein.—6s.—6s. 3d. per lb.

Potass. Bitartrate.—99/100% (Cream of Tartar) 100s. per cwt., less 2½% for ton lots.

Potass. Citrate.—1s. 11d.—2s. 2d. per lb.

Potass. Ferricyanide.—1s. 9d. per lb. in cwt. lots.

Potass. Iodide.—16s. 8d.—17s. 2d. per lb.

Potass. Metabisulphite.—6d. per lb., 1-cwt. kegs included. F.o.r. London.

Potass. Permanganate.—6d. per lb. spot.

Quinine Sulphate.—2s. per oz.; 1s. 8d. per oz. in 100 oz. tins (1000 oz. lots).

Resorcin.—3s. 9d.—4s. per lb. spot.

Saccharin.—55s. per lb., and lower in quantity.

Salol.—2s. 4d. per lb.

Sod. Benzoate, B.P.—1s. 10d.—2s. 2d. per lb.

Sod. Citrate, B.P.C., 1911—1s. 8d.—1s. 11d. per lb.; B.P.C., 1923.—2s. per lb.; U.S.P., 1s. 11d.—2s. 2d. per lb., according to quantity.

Sod. Ferrocyanide.—4d. per lb., carr. paid.

Sod. Hyposulphite.—Photographic, £15 5s. per ton, d/d. consignee's station in 1-cwt. kegs.

Sod. Nitroprusside.—16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt).—92s. 6d.—97s. 6d. per cwt. net. Crystals, 5s. per cwt. extra.

Sod. Salicylate.—Powder, 1s. 9d.—1s. 10d. per lb.; Crystal, 1s. 10d.—1s. 11d. per lb. Crystals 5s. per cwt. extra.

Sod. Sulphide.—Pure recryst. 10d.—1s. 2d. per lb.

Sod. Sulphite, anhydrous.—£27 10s.—£28 10s. per ton f.o.b., according to quantity, 1-cwt. kegs included.

Sulphonal.—6s. 6d.—6s. 9d. per lb.

Tartar Emetic B.P. cryst. or powder.—2s.—2s. 2d. per lb.

Thymol, Puriss.—10s. 6d.—10s. 9d. per lb., according to quantity. Natural.—15s. per lb.

PERFUMERY CHEMICALS

Acetophenone.—6s. 6d. per lb.

Aubepine (ex Anethole).—10s. 6d. per lb.

Amyl Acetate.—2s. per lb. Amyl Butyrate.—5s. 3d. per lb. Amyl Salicylate.—3s. per lb.

Anethole (M.P. 21/22° C.).—5s. 6d. per lb.

Benzyl Acetate from Chlorine-free Benzyl Alcohol.—2s. per lb. Benzyl Alcohol free from Chlorine.—2s. per lb. Benzaldehyde free from Chlorine.—2s. 6d. per lb. Benzyl Benzoate.—2s. 6d. per lb.

Cinnamic Aldehyde.—Natural, 17s. per lb.

Coumarin.—10s. per lb.

Citronellol.—14s. 6d. per lb.

Citral.—8s. 6d. per lb.

Ethyl Cinnamate.—6s. 6d. per lb.

Ethyl Phthalate.—2s. 9d. per lb.

Eugenol.—9s. per lb. Geraniol (Palmarosa).—18s. 6d. per lb. Geraniol.—6s. 6d.—10s. per lb. Heliotropine.—4s. 9d. per lb. Iso Eugenol.—13s. 6d. per lb. Linalol.—(ex Bois de Rose) 15s. per lb.—(ex Shui Oil) 10s. 6d. per lb. Linalyl Acetate.—(ex Bois de Rose) 18s. 6d. per lb.—(ex Shui Oil) 14s. 6d. per lb.

Methyl Anthranilate.—8s. 6d. per lb.

Methyl Benzoate.—4s. per lb.

Musk Ketone.—35s. per lb.

Musk Xylol.—8s. 6d. per lb.

Nerolin.—4s. 6d. per lb.

Phenyl Ethyl Acetate.—12s. per lb.

Phenyl Ethyl Alcohol.—10s. 6d. per lb.

Rhodinol.—32s. 6d. per lb. Safral.—1s. 6d. per lb. Terpeneol.—1s. 8d. per lb. Vanilin.—17s.—18s. per lb.

ESSENTIAL OILS

Almond.—10s. 3d. per lb. Anise.—3s. per lb. Bergamot.—28s. per lb. Bourbon Geranium.—14s. 6d. per lb.

Camphor.—70s. per cwt. Cananga, Java, 26s. per lb. Cassia, 80/85%.—8s. 3d. per lb. Cinnamon, Leaf.—6d. per oz. Citronella.—Java 85/90%, 1s. 11d. per lb., Ceylon, Pure, 1s. 9d. per lb. Clove, pure.—6s. per lb.

Eucalyptus, 75/80%.—2s. 3d. per lb. Lavender.—Mont Blanc 38/40%, 22s. 6d. per lb. Lemon.—8s. per lb. Lemon-grass.—4s. 6d. per lb. Orange, Sweet.—10s. 6d. per lb. Otto of Rose.—Anatolian, 30s. per oz., Bulgarian, 70s. per oz. Palma Rosa.—10s. 6d. per lb. Peppermint.—Wayne County, 18s. per lb. Japanese, 8s. per lb. Petitgrain.—7s. 9d. per lb. Sandalwood.—Mysore, 26s. 6d. per lb., 90/95%, 16s. 6d. per lb.

PATENT LIST

The complete Specifications notified as accepted are open to inspection at the Patent Office immediately, and to opposition not later than Sept. 3rd. They are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on July 21st. Complete Specifications marked * are those which are open to public inspection before acceptance. The remainder are those accepted.

I.—Applications

British Research Association for the Woollen & Worsted Industries, Barker, Fawcett, Hirst, and Tintometer, Ltd. Apparatus for colour estimation. 17,165. June 28. Churchill. Kilns. 17,283. June 29.

Electrolux, Ltd. Evaporators. 17,391. June 30. (Ger., 3.8.26.)
Fairlie. Furnaces. 17,500. July 1.

Gall. Optical pyrometers. 17,230. June 29.

Harter. Apparatus for carrying-out reactions between gases and vapours etc. 17,545. July 1.

I.-G. Farbenind. Production of aqueous solutions of organic compounds insoluble in water. 17,622. July 2. (Ger., 2.7.26.)

Johnson (I.-G. Farbenind.). Manufacture of highly-active adsorbents. 17,095. June 27. Purification of gases etc. 17,097. June 27.

Maschinenfabr. Beth. Bag filters. 17,009. June 27. (Ger., 11.12.26.)

Poleo Feuerlösch Apparate Ges. Fire-extinguishing compounds. 17,100. June 27. (Ger., 30.6.26.)

Robson. Heat-exchangers. 17,168. June 28.

Wood. Grinding apparatus. 17,154. June 28.

I.—Complete Specifications

8446 (1926). Silica Gel Corp. Adsorption apparatus. (255,819.)

10,000 (1926). Schucker. Apparatus for the hydrogenation of liquids. (273,045.)

15,834 (1926). Metallbank und Metallurgische Ges., and Gensecke. Working steam distillation plants. (273,092.)

16,766 (1926). Nairn. Mixing-machines. (273,101.)

17,041 (1926). Pease. Treatment of gases with liquids. (273,103.)

*19,226 (1926). Benson. Separation of mixtures of gases. (273,229.)

*14,095 (1927). Silica Gel Corp. Separation of a gas or vapour from a mixture. (273,261.)

*16,045 (1927). Brüner. Refrigerating method. (273,282.)

*16,318 (1927). Akt. Separator. Continuously treating liquids. (273,292.)

*16,395 (1927). Krupp Grusonwerk. Apparatus for expressing liquid constituents from materials. (273,294.)

*16,483 (1927). Morterud. Heating and evaporation apparatus. (273,298.)

II.—Applications

Algem. Norit Maatsch. Activated carbon. 17,657. July 2. (Holland, 3.7.26.)

Davidson and Patent Retorts, Ltd. Gasification of coal etc. 17,667. July 2.

Gessmann and Shadders. Production of low-boiling hydrocarbons. 17,441. June 30.

Goskar. Distillation of carbonaceous materials. 17,284. June 29.

I.-G. Farbenind. Manufacture of hydrocarbons. 17,092. June 27. (Ger., 26.6.26.) Manufacture of liquid products from coal etc. 17,093. June 27. (Ger., 29.6.26.)

Johnson (I.-G. Farbenind.). Treatment of exhaust gases. 17,291. June 29.

Roser. Distillation of fuel. 17,294. June 29.

Soc. Anon. Le Carbone. Cracking oils. 17,273. June 29. (Fr., 14.5.27.)

II.—Complete Specifications

5498 (1926). I.-G. Farbenind. Manufacture of hydrocarbons and derivatives from natural oils etc. (249,493.)

9862 (1926). I.-G. Farbenind. Manufacture of hydrocarbons and derivatives from coal, tars, mineral oils, etc. (251,264.)

12,835 (1926). Dempster & Sons, Ltd., and Toogood. Gas-retort plant. (273,063.)

14,142 (1926). Coppée et Cie. Coke ovens. (253,887.)

15,074 (1926). Chemical Research Synd. Cracking hydrocarbon oils. (253,562.)

15,295 (1926). Plassmann. Apparatus for distilling fuel, roasting ores, etc. (254,697.)

19,831 (1926). Allgem. Ges. f. Chem. Industrie. Purification of liquid hydrocarbons. (258,846.)

12,777 (1927). I.-G. Farbenind. Manufacture of hydrocarbons and derivatives from natural oils etc. (273,228.)

*8376 (1927). Humphreys & Glasgow, Ltd. Purification of gas. (273,250.)

*12,773 (1927). Cross. Motor fuel. (273,256.)

*17,092 (1927). I.-G. Farbenind. Manufacture of hydrocarbons from coal, tars, mineral oils, etc. (273,337.)

III.—Application

I.-G. Farbenind. 17,092—3. See II.

III.—Complete Specifications

9862 (1926). I.-G. Farbenind. See II.

19,831 (1926). Allgem. Ges. f. Chem. Ind. See II.

10,512 (1927). Cooper, Henshaw, and Holmes & Co., Ltd. Separation of water from mixtures of steam and vapours of benzene, toluene, etc. (273,224.)

*17,092 (1927). I.-G. Farbenind. See II.

IV.—Applications

Carmichael (I.-G. Farbenind.). Manufacture of carboxylic acids 17,573. July 1. Manufacture of dyestuffs. 17,574. July 1.

I.-G. Farbenind. Manufacture of benzanthrone condensation products etc. 17,293. June 29.

Imray (I. G. Farbenind.). Manufacture of derivatives of the triarylmethane series. 17,280. June 29.

Johnson (I. G. Farbenind.). Manufacture of vat dyestuffs. 17,091. June 27.

Newport Co. Preparing alkyl ethers of 3'-nitro-4'-hydroxy-orthobenzoylbenzoic acid. 17,201. June 28. (U.S., 28.6.26.)

IV.—Complete Specifications

1525 and 2774 (1926). I.-G. Farbenind. See VI.

7578 (1926). Soc. Chem. Ind. in Basle. Manufacture of dyestuff preparations. (249,549.)

9962 (1926). British Dyestuffs Corp., and Hailwood. Electrolytic desulphonation of anthraquinone sulphonic acids. (273,043.)

9922 (1927). I.-G. Farbenind. See VI.

*6306 (1927). I.-G. Farbenind. Manufacture of vat dyestuffs. (273,247.)

*16,511 (1927). I.-G. Farbenind. Manufacture of dyestuffs of the anthracene series. (273,299.)

*16,846 (1927). I.-G. Farbenind. See XX.

*17,201 (1927). Newport Co. Preparing alkyl ethers of 3'-nitro-4'-hydroxy-orthobenzoylbenzoic acid. (273,342.)

V.—Applications

*16,331 (1927). Rhenania-Kunheim Verein Chem. Fabr. Manufacture of fertilisers. (273,291.)

XVII.—Complete Specification

*16,732 (1927). Scholler. *See* V.

XVIII.—Application

Horst. Preparation of hop extract. 17,320. June 29.

XIX. Applications

Booth. Feeding-stuffs for cattle. 17,120. June 28.

Schreiber Products Corp. Food product. 17,322. June 29 (U.S. 24,227.)

XIX.—Complete Specification

6832 (1926). Internat. Oxygenum Maatsch. Treatment of meal, flour, etc. (249,139.)

XX. Applications

Carpmael (I.-G. Farbenind.). 17,573. *See* IV.

Johnson (I.-G. Farbenind.). Manufacture of unsaturated aliphatic hydrocarbons. 17,094. June 27. Manufacture of paraformaldehyde. 17,553. July 1. Production of lactic acid. 17,623. July 2.

Newport Co. 17,201. *See* IV.

Ruzicka and Shuttleworth. Manufacture of acetic anhydride etc. 17,577. July 1.

Soc. Anon. des Distilleries des Deux-Sèvres. Separation of fatty acids in dilute aqueous solutions. 17,543. July 1. (Belg., 1,726.)

XX. Complete Specifications

4589 (1926). Rath. Preparation of means for fighting bacterial diseases. (247,965.)

30,351 (1926). Chem. Fabr. vorm. Schering. Manufacture of symmetrical diarylguanidines. (262,155.)

13,124 (1927). I.-G. Farbenind. Manufacture of acid derivatives of the $\alpha\alpha'$ -dimethyl- γ -hydroxypiperidine- β -carboxylic acid esters. (271,467.)

*5555 (1927). Riedel A.-G. Manufacture of hydroaromatic di-carboxylic acids. (273,244.)

*14,211 (1927). Comp. de Bethune. Preparation of ethylsulphuric acid. (273,263.)

*15,681 (1927). Wecker. Manufacture of esters of fatty acids and of mixtures containing fatty acids. (273,276.)

*15,766 (1927). Chem. Fabr. vorm. Schering. Manufacture of mixed alkaloid salts. (273,279.)

*16,846 (1927). I.-G. Farbenind. Manufacture of cyclic ketones. (273,321.)

*17,201 (1927). Newport Co. *See* IV.

XXI.—Applications

Berthon. Films for colour photography. 17,198. June 28. (Fr., 20,726.)

Gratama and Meursing. Light-sensitive paper etc. 17,576. July 1. (Ger., 7,726.)

I.-G. Farbenind. Photographic films. 17,102. June 27. (Ger., 9,926.)

Martinez. Colour photography. 17,174. June 28.

Merejkovsky. Photographic developers. 17,254. June 29.

Soc. Civile pour l'Etude de la Photographie et de la Cinématographie en Couleurs. Photographic films etc. 17,328. June 29. (Fr., 6,527.)

XXI.—Complete Specification

7510 (1926). Thomson. Kinematograph colour films. (272,986.)

XXII.—Application

Eschbach. Igniting explosives. 17,446. June 30. (Ger., 1,926.)

XXIII.—Application

Gordon, and Gordon & Co., Ltd. (Hall). Filtration of alkaline waters. 17,215. June 28.

XXIII.—Complete Specification

7068 (1926). Hadfield. Treating residues obtained from house refuse. (272,981.)

GENERAL NOTES**Official Trade Intelligence**

The Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W., has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and stating the specific reference number:—
Australia: Hollowware, glass (1); water-tube boilers, steel (A.X. 4850); crockery (Commercial Bureau, Australia House, Strand, W.C. 2). *British India*: Galvanised wrought iron, mild steel (A. 4862). *Bulgaria*: Pig iron (A. 4871); iron (A.X. 4877). *Canada*: Steel sheets, brass and copper sheets, tinplate (4); paper (5). *Egypt*: Leather (16). *France*: Printing material (7). *Greece*: Soya bean oil (9). *Holland*: Leather (11). *South Africa*: Glass water containers (B.X. 3611); printing paper (B.X. 3612); steel plates (A.X. 4874). *Turkey*: Paper (B.X. 3609). *Uruguay*: Sanitary ware (19). *Yugoslavia*: Hides (13).

Merchandise Marks Act Enquiries

The Board of Trade have referred to the Standing Committee appointed by them under the Act applications for Orders in Council to be made requiring indications of origin to be given in the case of imported pottery. A public inquiry will be held later by the Committee, of which the secretary is Mr. E. W. Reardon, New Public Offices, Great George Street, London, S.W.1.

Petroleum Spirit (Conveyance) Regulations, 1927

In pursuance of Section 9 and the Third Schedule of the Petroleum Act, 1926, the following regulations have been made for the conveyance of petroleum spirit by road:—(1) The requirement in No. 1 of the Petroleum Spirit (Conveyance) Regulations, 1926, (a) that any vehicle on which petroleum is conveyed shall be constructed with sides and back of adequate height, shall not apply to horse-drawn vehicles if the load is securely fastened to the vehicle and all vessels of two gallons' capacity and under are packed in wooden cases. (2) Notwithstanding the requirement in No. 6 of the said Regulations that, if the capacity of the tank exceeds 1500 gals., the weight of the engine and load shall be distributed over the three axles of a six-wheeled combination vehicle (tractor and trailer), it shall be lawful to use vehicles of other types, if approved by order of the Secretary of State as suitable for the conveyance of quantities exceeding 1500 gals. (3) These Regulations may be referred to as the Petroleum Spirit (Conveyance) Regulations, 1927.

New Dyestuffs by Scottish Dyes, Ltd.

Scottish Dyes, Ltd., have issued a pattern card of four new Caledon colours—Olive 3G, Olive 2B, Grey 3G, and Grey RRH. These colours, on account of their good shades, excellent level dyeing properties, and fastness to light, fill several gaps in this part of the fast vat range. They are specially suited for cotton piece dyeing and for artificial silk, but are not recommended for goods which have to withstand a full bleach. The method of dyeing is from a hot strong caustic vat. Their level dyeing properties make them particularly suitable for shading purposes.

New B.D.C. Dyestuffs

The latest pattern card of the British Dyestuffs Corporation, Ltd., illustrates fashionable shades for autumn, 1927. The first issues of seasonal forecasts were so very successful, and the demand for copies so great, that their regular issue will be a permanent feature of the Corporation's business. The shades shown on the present pattern card represent The Drapers' Organisation forecast for autumn, 1927.

Chlorazol colours on cotton yarn is the subject of a recent pattern book issued by the British Dyestuffs Corporation, Ltd., in which illustrations of Chlorazol colours on cotton yarn are given. Information is given about the use and after-treatment of these colours, and lists are given of Chlorazol colours suitable for Celanese resist work. Tables are also given showing the fastness of the various colours to light, light washing, acids, alkali and discharge.

A new pattern card draws attention to the new B.D.C. colour for cellulose acetate silk—Duranol Blue R. Paste. This colour gives full reddish blue shades of good fastness to light and excellent fastness to washing. It possesses very good fastness to rubbing and hot pressing, and will be found suitable as a basis for royal and navy shades on all forms of cellulose acetate materials, and can be used in combination with other Duranol and Ionamine colours.

B.D.C. dyestuffs for vegetable tanned leathers are illustrated in a recent pattern card. Information is included with regard to the preparation of skins for dyeing; principal methods of leather dyeing under the headings (1) tray dyeing, (2) paddle dyeing, and (3) drum dyeing. This is followed by the dyeing process, particulars which deal with the dissolving of colours and the production of shades other than those illustrated on the pattern card. In addition to the dyestuffs illustrated, the British Dyestuffs Corporation, Ltd., have a full range of dyestuffs for the colouring of every other class of leather.

Another recent pattern card of the British Dyestuffs Corporation illustrates Thionine Blue G.O. This basic dyestuff is suitable for dyeing cotton piece on a discharged tannin mordant, and gives very good white effects. Thionine Blue G.O. withstands the action of reducing agents, and is specially adapted for the colouring of rongalite (formosul) or tin discharges on dischargeable direct dyed grounds. It is also used extensively for the production of blue resists under aniline black. In the discharge and resist styles it is distinctly superior to the methylene blues, since the shade of Thionine Blue G.O. is much less affected in the process.

A further addition to the B.D.C. range of acid colours—Naphthalene Fast Black 4B—has also been issued. This colour is of interest to wool dyers in general, particularly for the dyeing of wool hosiery yarns and material for knitting purposes generally, since it gives a full bloomy tone with good fastness to washing. It is also used in the dyeing of hat bodies, possessing good penetrating qualities and fastness to water, being, in the latter respect, superior to the average acid black. In addition, it is not affected by dyeing in copper vessels. It will prove of interest to the garment dyer, as it dyes wool and silk fairly well from a neutral dyebath.

News from Advertisements

No. 29

EDITORIAL

Fuel Research

DESPITE the many physicians who have deliberated over the sickness of the coal industry, despite the surgical wisdom which has advised the removal of diseased areas, the industry can hardly be said to be in a satisfactory condition. It is, indeed, a difficult industry from the economic point of view, but it is of too vital national importance for anyone to view its troubles with indifference. Unfortunately, it seems that foreign users of British coal have been learning to do without it on account of the coal stoppage, and our neighbour across the Channel has found it necessary, faced with large accumulated stocks, to restrict importations. It is not easy to suggest remedies for economic troubles, but the Report of the Fuel Research Board, which has just been issued, shows conclusively how the weaknesses in the scientific foundations of the industry are being laid bare, how the applications of its products are being investigated with a thoroughness and a competence that is worthy of our best scientific traditions. Progress in the work of the Board was naturally delayed by the coal stoppage, but much has been done nevertheless. The organised work of the physical and chemical survey of the national coal resources is increasing in scope and value. Investigations are in progress to elucidate important problems such as those pertaining to the purification of coal, sampling and analysis, coal ash, the primary decomposition and maturing of coal, the reactivity of coke, and so on. The low-temperature carbonisation process of the Fuel Research Station has reached such a stage that Sir D. Milne Watson (as we record in the summary of the Report which we publish on another page), on the advice of his staff, selected it amongst all the processes developed in this country and on the Continent, as the one most promising for development in conjunction with a gas works. The decision to form the Fuel Production Company is recorded elsewhere in these columns, and it is gratifying to note that it will now become possible to determine the economic aspects of low-temperature carbonisation through this arrangement, which the Gas Light & Coke Company is, in effect, carrying out for the benefit of the whole industry. We learn that the Bergius process is applicable to British coals, though its economic possibilities are still unknown. They are being investigated, however, as are the possi-

bilities of the synthesis of alcohols and hydrocarbons from carbon monoxide and hydrogen. Many more matters of the greatest importance are discussed in the Report, which should be read, not only by those interested in the carbonisation industries, but by all who take thought for the future of our country.

Potash from Palestine

The importance of adequate manuring of the soil is fully realised in the modern agricultural world, but the education of the farmer has been no simple task, and many harvests have been garnered since Van Helmont watered and weighed so assiduously during his pioneer experiments in the realm of plant physiology. Lawes and Gilbert explained the fundamental requirements of the plant for nitrogenous, phosphatic and potassic fertilisers, and the artificial fertiliser industry may be said to date from the time when these notable British investigators carried out their work.

Britain has always been able to provide her own supplies of nitrogenous fertilisers—and to have an exportable surplus—and in these latter days of more intensive manuring the development of a synthetic nitrogen products industry—the history of which has been so well told by Colonel G. P. Pollitt in his recent Messel Memorial Lecture—has assured us of unlimited supplies. Further, although the British superphosphate industry has passed through troublesome times, there is no need to fear a famine in regard to home phosphate fertilisers.

We have unfortunately never had an assured supply of British or Empire potash, and it is well known that Germany held a monopoly in this field in pre-war days—although small amounts of potash salts were produced in Poland, Italy and Spain. Any considerable manufacture of potash from seaweed ceased long ago, except perhaps in Japan.

The return of Alsace-Lorraine to France by the terms of the Treaty of Versailles brought under French control potash salt beds containing an amount of potash estimated at about one fifth that of the German deposits, and it is therefore natural that production in France has been substantially increased in recent years. When the Alsace deposits were under German control a maximum amount of 58,000 tons of potash per annum was

raised. This has increased to 330,000 tons in 1926 through the stages of 195,000 tons in 1920 and 270,000 tons in 1923. As is well known, a Franco-German agreement now exists, the terms of which we need not consider at the moment.

Again, Poland is increasing her output of potash and actually mined 200,000 tons in 1926, whilst the appearance of Russia as a potash exporter is not unlikely, for she possesses extensive deposits, and has made small amounts of the material from sunflower stalks. Outside Germany and France, however, the most interesting potash producer is the United States, where, in spite of the fact that such war-time sources as cement kiln dust, blast furnace dust, seaweed and molasses have ceased supply to all intents and purposes, a large and increasing amount of potash is being recovered from natural brines. It is sufficient to recall the story of the Trona Corporation's enterprise at Searles Lake, California, as described in our columns some weeks ago by Mr. John E. Teeple. His graphic description of the success which has attended the efforts of chemists and engineers under his inspiring leadership may be condensed into the simple facts that hundreds of tons of potassium chloride are being made every week, together with borax, sodium sulphate and carbonate in large amounts.

Neither Britain nor any part of the Empire has found or developed any substantial source of potash salts with which to supply agricultural demands until quite recently, when the immense resources of the Dead Sea in Palestine claimed serious attention. The Colonial Office Committee which was appointed to investigate the possible commercial utilisation of Dead Sea brine for the manufacture of potash salts reported no insuperable difficulty from the technical point of view, and suggested a production of 100,000 tons of potash salts per annum. Major Brock, too, has estimated the potential resources of Dead Sea potash as two thousand million metric tons, that is to say, almost an illimitable amount insofar as British and Empire agriculture is concerned.

The pumping of the brine, its evaporation in natural clay-lined lagoons by solar heat and the working up of the crude residue into saleable salts—potash fertilisers, bromine salts, common salt, etc.—are matters which should be of little concern to experienced chemical engineers, but the problem of transport will demand careful attention. The nearest railway is at Jerusalem, some thirty miles away from the sunken Dead Sea, three thousand feet below the level of the railway. A historic road there is, it is true, but romance in itself will not carry potash, and considerable expense will need be involved before the crude potash salts can be made available for commercial handling. None the less, it has been conservatively reckoned that such salts could be put on board ship at Jaffa at an overall cost of under £4 per ton.

Two years ago the Colonial Office and the Palestine Government, with a sure knowledge of the possibilities, invited tenders for concessions to work the Dead Sea brines, and recently it has been announced that the Palestine Government has granted a concession to Messrs. Nowomesky and Tulloch for the manufacture of potash and other salts from Dead Sea brine. It is understood that one of the terms of the concession concerns the

building of a railway track to link up with existing services, but as yet we have seen no details.

The Pipe of Peace

When the curiosity of the chemist impels him to investigate the non-volatile acids of the strawberry or peach, the flavouring, odorous or colouring principles of the vanilla bean, the musk sac or the leaves of *indigofera tinctoria*, respectively, there may be occasionally an ulterior "mercenary motive," the detection of which we are content to leave to the keenly critical eye of an eminent professor. Frequently, however, investigations are inspired by a desire to unfold knowledge which shall be of value to mankind at large in his struggle against a self-created environment. Into this class probably fall the studies which have been carried through by Roe E. Remington in the laboratories of the Department of Biological Chemistry of the North Dakota Agricultural College, U.S.A., upon the arsenic content of tobacco. It has been found that samples of American smoking and plug tobacco contain 6 to 30 parts of arsenious oxide per million. Approximately half the arsenic in pipe tobacco is evolved in the smoke, whilst half of that in plug tobacco is soluble in water. The amounts of arsenic present in tobacco are therefore considerably higher than those permitted in foodstuffs under the legal codes of civilised countries, and higher than those found by British investigators in the innocent oyster. It is not known yet what portion of the arsenic of tobacco passes into the system of the smoker, but further investigations will be awaited with interest, especially when it is remembered that the analytical programme which followed the Manchester beer scare many years ago revealed a maximum amount of arsenic in any sample of four parts per million.

The painstaking work of Billeter and Marfurt appears to have established the fact that the human adult body contains about one-ten-millionth of its weight of arsenic. This is derived from foodstuffs which become contaminated by reason of chemical treatment during manufacture or which, as in the case of plants or certain sea products, contain arsenic originally. Often, however, the amount of arsenic found in human blood cannot be explained upon the basis of the arsenic content of foodstuffs, and it is a point of no little interest that a previously unsuspected source of arsenic in human environment has been discovered. If there should appear any sign of a tobacco scare by reason of the appearance of garbled versions of Remington's work in the daily press, we are confident that chemists will set a noble example by refusing to put out their pipes. Indeed, when Prof. Armstrong published the results of his investigations upon the carbon monoxide content of tobacco smoke in the *British Medical Journal* a few years ago, and proved to all sensible chemists that tobacco smoke contained as much of this poison gas as did the gas piped by the South Metropolitan Gas Co., we noticed no diminution in the intensity of the smoke haze which dignified subsequent scientific meetings. Worshippers at the shrine of My Lady Nicotine will be interested in, but in no wise appalled by, the discovery that tobacco contains more arsenic than do crayfish. And anyway, most of us don't chew.

THE CONTROL OF COMPONENTS FOR MAGNESIUM OXYCHLORIDE CEMENTS

By A. W. COMBER, F.I.C., Assoc.Inst. M.M.

During the past twenty years there has been a remarkable development in the use of magnesite compositions for the covering of floors and walls, particularly in the United States. As generally known, these compositions consist of a mixture of calcined magnesite with inert material, such as sawdust or wood flour for floors and sand for stucco work on walls. Preferably, there should also be a definite proportion of finely powdered quartz or silica as a filler. When moistened with a strong solution of magnesium chloride, such a mixture sets fairly rapidly, to form a hard mass of high mechanical strength.

The industry is young, and until a few years before the war, was mainly confined to Austria and Germany. One of the earliest floors of this type to attract public attention was laid in the Austrian pavilion at the Chicago World's Fair in 1893. An industry has since arisen in the United States which is now among the most important in the country. It is interesting to note that at the present time something like 75% of the magnesite used there in the form of oxychloride cements is accounted for by the requirements for stucco and plaster, the balance being for floors.

The publicity literature of some of the American firms would be a revelation to users of magnesite compositions in Britain, where, although the flooring industry has in a measure been established, the application of similar mixtures for covering walls has not yet made any progress. This has been chiefly due to lack of enterprise, but in part may be ascribed to theoretical and ill-founded objections based on the fancied unsuitability of our climate.

Perhaps this statement should be qualified by reference to a novel demonstration at the Building Exhibition in London last year. There was shown a section of one of the standard steel houses, with the plates masked externally with stucco and internally with coloured plaster, both being preparations of magnesite. In view of the aesthetic and practical advantages of these materials in such a connexion, the success of this effort would open up a field of exceptional interest and promise.

The growth of the industry in the United States is undoubtedly due to the early appreciation of the need for standardisation of materials and methods in order to secure uniformity of results. An instance of American enterprise is shown in the activities of the Dow Chemical Company, of Midland, Michigan. This firm makes magnesium chloride, and to this extent is directly interested in the technical and commercial development of the industry upon sound lines. It has therefore established well-equipped chemical and physical laboratories and even a calcining plant, where a staff of experts is engaged on research into the problems and possibilities which the extending use of magnesite preparations for structural work continually offers. The Dow series of bulletins embodying the results of this work is of inestimable value.

It is remarkable that in our own country, neither through the technical press nor the publications of the

scientific societies, has there appeared much information of importance concerning original work in a field which offers such promise. Rule of thumb methods still prevail, and the effect is not to the advantage of the industry.

It is true that many excellent and apparently permanent floors have been laid by firms of deserved reputation, but it is none the less evident that there is still a regrettable lack of certainty in obtaining consistently good results. Faults develop, either in the early stages or after considerable lapse of time. The cause is often obscure, and in many cases may be untraceable by the contractor. The trouble is not always due to bad workmanship, although there is room for improvement, not only in the composition and grading of mixes, but also in methods of manipulation. Often the blame lies with one or more of the components used, and the most important of these is the magnesite.

The term magnesite is more properly applied to the mineral, natural carbonate of magnesium, and its association with the calcined product of commerce is academically incorrect. The name, however, has come into common use as a trade description, and it is used here in the sense in which it is popularly understood.

Raw or mineral magnesite is calcined in specially designed kilns to yield, with loss of carbonic acid gas, the oxide magnesite. Calcination at a relatively low temperature produces "caustic" or cementitious magnesite. At a considerably higher temperature the product is "dead-burnt" or refractory magnesite, with which we are not at present concerned.

Existing methods of calcination are open to improvement, partly along the lines of kiln design, but chiefly in the direction of kiln control. Given a certain standard of raw magnesite, the production of satisfactory calcined material is entirely a matter of precise kiln operation, and although much of the product reaching the market is quite satisfactory for its purpose, it is a matter for some concern that calciners do not yet seem able to supply a uniformly standardised caustic magnesite. It has been established that chemical analysis of the commercial material is only of service within very narrow limits, and that conclusive information on the suitability of a calcined magnesite for cement or plaster can only be obtained by physical and mechanical tests of its behaviour under working conditions.

The value of a calcined magnesite is dependent upon the proportion of *reactive* magnesia contained in it. Exactly what chemical or physical condition causes this potential activity has not yet been demonstrated, but it may be definitely stated that a magnesite showing a content of, say, 90% magnesia, which under the present loose standard is considered to be first grade material, may actually contain a lower proportion of reactive constituent than another sample giving on analysis 80%, or even less.

Almost equally important is the form in which the lime is present in the calcined product. Calcination should be so conducted that the temperature does not reach the point of dissociation of the calcium carbonate, which is always present to some extent in the mineral. Any appreciable proportion of free lime is demonstrably harmful, but ordinary analysis does not indicate

whether the lime is present in this form, or combined as carbonate.

Because of the failure to appreciate the essential importance of such factors as these, a specification based upon chemical analysis is still the only one recognised in this country. It is possible, as things are, for a sample of calcined magnesite to be rated as inferior, or even condemned, on chemical test, but to be capable of giving much better results in practice than another which analysis alone would indicate to be of the highest quality.

The development of the magnesite flooring industry and its natural extension to the use of similar materials for covering walls must depend upon the maintenance of a consistently high standard of results, but every reputable flooring contractor realises that this is not so certain of attainment as he would wish. Many of the difficulties now experienced can undoubtedly be attributed to the uncertain quality of commercial calcined magnesite, and it is very desirable that this hazard of the market should be removed.

A standard mix should be formulated, not necessarily for use under ordinary working conditions, which are not always the same, but it should approximate to one which would meet average needs. Then this mix of the magnesite under test, together with standardised components, should be examined for qualities specified to meet an agreed schedule. These may include setting time, expansion or contraction during a stated period, resistance to abrasion and for special conditions, tensile strength and behaviour under compression. Tests for water resistance and a knowledge of behaviour under intermittent and prolonged exposure to a moist atmosphere would also be desirable.

Examples of standard mixes used in the United States for these tests are as follows:—

Flooring mix	Parts by weight
Calcined magnesite	5
Powdered quartz	5
Wood fibre	1
Talc	1
Red oxide of iron	1
Stucco mix:	
Calcined magnesite	1
Powdered quartz	2
Sand (between 20 and 30 mesh)	5

It will be evident that a knowledge of the chemical composition of the magnesite will only be of subsidiary importance. It is not, however, to be expected that every floor layer will be in a position to make these tests for himself, but it is in his interest that he should appreciate exactly what he needs for consistently good work. Nor, indeed, would it be practicable for the calciner to make such an intensive examination on every batch sent out, but it is not unreasonable to ask that he should definitely inform himself of the properties of the product offered, and so be in a position to guarantee that this will conform in grade with a fair specification of quality. Exact knowledge of the behaviour when tested on the lines indicated of a magnesite calcined under known conditions should go a long way in the effort to reach a standardisation of kiln operation with a consequent uniformity in quality of output.

Magnesite for oxychloride cements should be ground to a definite degree of fineness, and this degree should

be precisely stated by the seller. A fair standard is for not more than 5% to be retained on a 120-mesh screen, and it can, with advantage, be finer than this. It is not realised to what extent uneven or insufficient grinding is itself a cause of failure. Whether a buyer is able to insist upon a more stringent specification or not, he can at least determine if his magnesite is properly ground. He can get a suitable screen at small cost and test for himself the fineness of any product which may be offered to him.

There is not the same amount of uncertainty with the other components of a normal mix. Where wood flour or sawdust is used, this should be standardised for texture or fineness, and even for source of supply. Woods vary in their power of absorption and resistance to decay, and their possible effect, not only in the early stages, but on the ultimate life of a floor, is well worth studying, but this will take time. If the wood, in whatever form it is used, be pretreated with magnesium chloride solution, the strength of this, the extent of saturation, and both the time and the conditions of storage should be made constant factors in the operation.

Finely ground quartz or silica is often used as a filler on both theoretical and practical grounds, and it is always a desirable constituent. The principle of "voids" which underlies the successful compounding of Portland cement mortar and concrete applies with equal force to magnesite mixtures, although the actual setting processes of the two types are different. The particle size of the silica should, therefore, bear a definite relation to that of the magnesite, and it follows also that the proportionate quantities of the two components should be on a determined basis. Broadly considered, a principal object of the fine silica filling is that it should act as a retarder to moderate quick setting and consequent excessive expansion, which would result from an undiluted mix of caustic magnesite.

The use of natural colouring matters is largely a question of individual choice, but it should be remembered that, apart from acting as inert diluting agents in the mix, these may, in certain circumstances, enter into combination and so affect, probably adversely, the later behaviour of a floor. It follows, therefore, that the more concentrated these agents are in colour value the better they will be for the purpose, as the proportion of pigment in the mix should be kept to the minimum amount which will give the desired result. For instance, red oxide of iron is a better medium than ochre.

Magnesium chloride is mainly imported from Germany, and comes to the market in what is known as the "6-molecule" or hydrated form. It should contain about 46% of actual magnesium chloride, the balance being water. Commercial magnesium chlorides have been found to contain undue amounts of sulphate, and also chlorides of calcium and the alkalis. These not only detract from the working efficiency of the solution by giving a misleading figure for specific gravity, but may be the direct cause of defects, such as efflorescence on a finished surface, and in extreme cases might modify setting action to such an extent that risk of early disintegration would follow. Magnesium chloride can readily be obtained of a satisfactory degree of purity, but buyers should press for a guarantee of actual content, and also for

stated maxima of usual impurities, such as calcium chloride, magnesium sulphate, and salt.

Magnesite composition floors are already a matter of regular specification in modern building practice, and several of the more responsible contractors, with some years of experience behind them, have attained a fair measure of consistency in their results. There is still, however, an avoidable element of uncertainty. The future of the industry is practically whatever those who are interested choose to make of it, for it is certain that, with a better understanding of the technical problems involved in the initial calcination and later preparation and selection of components, of the need for precision when compounding mixes, and of the mechanical and physical factors of the setting process, the present decade will witness a very extensive development in the use of magnesite compositions, not only for floors, but also in the form of stucco and plaster, for walls.

THE REPORT OF THE FUEL RESEARCH BOARD, 1926*

In its review of the past year's work, the Fuel Research Board remarks on the more general public interest in fuel questions generally, and refers to the addition of the Fuel Section of the Society of Chemical Industry and the Institute of Fuel to the specialised organisations which now deal with the study of fuel. It is stated that the technical difficulties of the low-temperature carbonisation of coal have been largely overcome, but the difficulty is an economic one. Much consideration was given to the need for a lengthy test on a commercial scale under commercial conditions. Processes which produce the largest proportion of lump coke suitable for domestic use also produce large quantities of rich gas, and if such a process were adopted throughout the country very large quantities of gas would be produced, the full value of which would only be realised with the co-operation of the gas undertakings. It was accordingly decided by the Government that Sir D. Milne Watson, the Governor of the Gas Light & Coke Co. and the President of the National Gas Council, should be asked for his assistance, and that the matter, being a question of commercial development, should be handled by the Mines Department, with the Department of Scientific and Industrial Research as technical advisers. Sir D. Milne Watson reported that, after examination of all the processes being developed in this country and on the Continent, he considered the one developed at the Fuel Research Station was the most promising for development in conjunction with a gas works, and made certain offers of co-operation. It was finally arranged to form a subsidiary company, the "Fuel Production Co., Ltd.," the capital of which has been guaranteed under the Trades Facilities Acts. The Gas Company will act as managers for the Fuel Co., and will bear all running and management costs. At the end of 1930 the Gas Co. will have an option to purchase the plant, or they may clear the site and dispose of the plant, etc., on behalf of the Fuel Co. It is hoped that the plant will be at work during next winter. Full records will

be kept, and full details will eventually be published and be freely at the disposal of any company wishing to use the process.

Dealing with the work on the production of alcohol from cellulosic materials, it is stated that though a process for the hydrolysis of pentosans and the fermentation of pentoses has been worked out, the process could only be successful, if at all, in other parts of the Empire, and it has been decided to discontinue the work. A full report is being prepared.

THE REPORT OF THE DIRECTOR OF FUEL RESEARCH

Dr. Lander points out that, although the coal stoppage interfered with large-scale work at the Fuel Research Station, definite progress was made with the experiments on low-temperature carbonisation. Work was carried out with the new horizontal retorts, and considerable progress was made with the laboratory researches.

The work of the physical and chemical survey was delayed by the coal stoppage, but progress was made in various areas. The microscopical examination of coal seams has been continued in the Lomax Palaeobotanical Laboratories, and Mr. C. A. Seyler is further developing his microscopical method for the study of the structure of coal. A revised report on the sampling and analysis of coal has been issued. A new method to determine phosphorus in coal has been recommended, and work is to begin on the occurrence of arsenic, silica, titanium, vanadium, etc. in coal ash and their effect on the determination of phosphorus. Methods of procedure have been recommended for sampling coal, but the question of sampling large consignments is still under consideration.

Some trials with vertical retorts on the effect of greatly increased throughput were made before coal became short, and some interesting results were obtained. The gas was of higher calorific value, and the yield was higher per retort per day, but less per ton of coal, whilst the yield of tar and ammonia per ton was greater. In view of the reduction of the thermal yield of gas per ton of coal, the process would hardly be economical. The new horizontal retorts were put into commission, but, owing to the coal shortage, no regular tests were carried out; investigations are now in progress.

About 200 methods of low-temperature carbonisation have been proved to the laboratory stage: a few are being developed on sound lines, most having reached the stage of intermediate-scale plant; 5 or 6 are in the stage of trial with a full-scale unit of, say, 5 to 100 tons daily capacity; 2 or 3 are being worked on a commercial scale, but none can produce audited figures to show that actual profits have been made under normal working conditions. It is again emphasised that no one system is likely to be exclusively adopted; the type of plant adopted will depend on the object aimed at, the raw material available, and local circumstances. Emphasis is laid on the magnitude of the task of developing fuel treatment to the point at which the 30 or 40 million tons of raw coal burned annually in domestic grates is replaced by low-temperature coal. Such a replacement would involve the starting of a new industry comparable in size with the existing carbonisation industries. The cost

* Department of Scientific and Industrial Research, pp. vi + 62. H.M. Stationery Office. Price 1s. 3d.

of plant would be at least £60,000,000, and the gas made would considerably exceed the total now made by the gas undertakings, so that the co-operation of the gas undertakings will be essential for the development of low-temperature carbonisation on a national scale.

The "E" low-temperature retorts have now worked a year with considerable success, and the plant is now considered to be approaching the end of that stage of development comprising trial with a full-scale unit. The construction of the plant, which is the one chosen for trial by the Fuel Production Company, mentioned previously, is described in the report, which states that the "E" retorts, when cooled down, were found to be in excellent condition, though the lower halves had bulged somewhat. The working temperature was 625° C., and the question of providing a cast iron which will withstand a higher temperature has been investigated with the aid of Prof. H. C. H. Carpenter and the co-operation of the British Cast Iron Research Association. Two new retorts have accordingly been designed, and will replace two narrow "D" retorts.

Further exploration has been made of the possibilities of carbonising finely divided coal (*e.g.*, the McEwen & Runge process). Experiments have been made on the effect of the temperature of carbonisation on the yields of products: the work is still proceeding. Examination of the low-temperature tar from the vertical retorts has been continued, and from a comparison of the ordinary distillation method of separation with the solvent method of separation, it is considered doubtful whether any advantage can be claimed for the latter; as the two methods yielded, as regards the oils, products which did not differ greatly. Investigations on the constituents of distillates from low-temperature tar are in progress at the Chemical Research Laboratory, Teddington, and a preliminary examination of the higher phenols has been made at the Fuel Research Station.

From inquiries as to the behaviour of low-temperature coke made in the "E" retorts, it appears that the coke gave general satisfaction to purchasers. Other work relates to briquetting fine coal, the properties desirable in pitch for use as a binder, the use of "pulp" binders, and various problems of the purification of coal.

The possibilities of producing oil from coal by the Bergius process have been actively investigated. The results prove that the British coals examined are suitable for the treatment, the yields from typical bituminous coals being about: Crude oil and spirit, 50–60%; gas, 20%; partially converted organic matter, 15%; the remainder being water and inorganic matter. On distillation, 20–25% of the oil remains as pitch. These figures compare with, say, 10%, or less, oil-producing tar obtainable from similar coals by low-temperature carbonisation.

The Fuel Research Station Bergius plant, now working, is capable of treating 1 ton of coal a day. A large amount of hydrogen—about 6% by weight of the coal—is required for the process, and the possibility of obtaining the bulk, if not all, of the necessary hydrogen from the gaseous products of the process is being investigated. The Bergius process is considered to be approaching the end of the stage of trial with intermediate-scale plant as far as British coals are concerned, though it

may have entered the stage of large-scale trial in its application to other raw materials. Dr. W. R. Ormandy, with assistance from the Department, has been investigating the nature of the light spirit obtained by the hydrogenation of coal, and has developed new methods for the determination of the hydrocarbons present. Bergin spirit has been found to have considerable "anti-pinking" properties. Further work is being carried out on the catalytic synthesis of alcohols and hydrocarbons from mixtures of carbon monoxide and hydrogen (*e.g.*, water-gas), and, in this connexion, the methods of purifying water-gas are being investigated.

The study of the reactivity of coke continues actively, and plans are being made to co-ordinate the work of the local Coke Research Committees which have been formed in several districts. Prof. W. A. Bone, F.R.S., is investigating the reactions in the blast furnace, and has obtained results which have added to our fundamental knowledge of the subject, and may prove of considerable practical importance.

Other work recorded relates to internal combustion engines, to domestic heating, power alcohol (previously mentioned), laboratory investigations in progress, and to miscellaneous work such as investigations on coal ash, the primary decomposition of coal, and the maturing of coal (which is being investigated under the direction of Professor Bone).

ANNUAL REPORT ON ALKALI &c. WORKS 1926*

The Chief Inspector, Mr. T. Lewis Bailey, reports that 1152 works were registered in 1926, comprising 1867 separate processes which had to be inspected, there being a reduction of 25 works and 61 processes compared with the previous year. Visits of inspection to registered works numbered 3661, and 2068 determinations of the noxious constituents of chimney and other gases were made. Various complaints concerning non-registrable processes were also investigated. The effect of the new Smoke Abatement Act is considered, and it is pointed out that the Act authorises an inspector to enter and inspect any work likely to cause the evolution of a noxious or offensive gas, even if the Alkali etc. Works Regulation Act, 1906, does not apply to such work. Fourteen complaints—considerably fewer than during 1925—were received, four relating to non-registrable processes, and two to dust nuisances. In one nuisance alleged against a registered works, repair of a subsidiary flue was being carried out while the main process was in operation, the result being the emission of an excessive amount of sulphur dioxide.

There were 46 alkali and copper (wet process) works, a decrease of five. The Leblanc process for the manufacture of salt cake and hydrochloric acid continues to be operated steadily. The plants are carefully operated, and there is an increasing tendency to improve the efficiency of acid recovery as far as possible with the small existing margin. Low-level escapes of acid fume are fewer. The newer mechanical furnaces are still on trial. Silica ware for the condensation of hydrochloric acid is making headway to some extent. Copper (wet pro-

cess) works are still operated only to a very limited extent.

Cement works were very active until the price of fuel became prohibitive. More 250 ft. rotary kilns were brought into operation. Provision is made in the latest designs to pass the coal dust direct to the kiln by a hot-air blast, thus removing a possibly source of nuisance; the adoption of induced draught, to supplement chimney draught, is extending. No complaints of smoke or dust from registered cement works were received. In some works special means are adopted to prevent emission of dust during grinding and packing. Electrostatic methods of depositing cement dust are now being adopted.

In smelting works the average acidity of the chimney gases is steadily getting lower, and the satisfactory treatment of the gases evolved in roasting zinc blende, referred to last year, continues. It is desirable that we should be able to deal with certain calciner gases lower in sulphur dioxide content than those already being treated. The problem is difficult, but there is some sign of progress, though not beyond a partial recovery in special cases. There were two cases of high acidity of the gases from the calcination of tin ores; in one, satisfactory results were obtained by washing the gases with alkaline (lime) showers; in the other, proposals have been made which should affect improvement without undue cost. Two complaints were received against smelting works; in one, a new process was being started, and satisfactory conditions could not be attained for a while; the other related to unpleasant smells.

The operation of sulphuric-acid units gave no cause for complaint, and the few infractions noted were due to temporary disorganisation. The average total acidity of exits from these plants was 1.08 in terms of SO_3 g. per cb. ft., ranging from 2.71 to 0.28. In last year's report, after a consideration of various points relating to the lead chamber reactions, with special reference to nitre consumption, attention was drawn to the possible conditions existing in the neighbourhood of steam jets and water sprays. In this connexion it is of particular interest to record the experience of Dr. J. Fischler, Trzebinia, Poland, regarding the use of acid sprays instead of water sprays over a period of three years ("Z. f. angew. Chemie," 39, 55, 1926). The change has brought with it not only advantages as regards average concentration of the acid formed, but the average nitre consumption has fallen considerably, notwithstanding the increased output per unit of chamber space.

In extension of the laboratory work described in last year's report, it has now been possible to carry out a number of experiments on actual Gay Lussac tower exit gases. The desire was to ascertain what actually takes place under different conditions, when Gay Lussac exit gases, normal and abnormal, are subjected to scrubbing with a limited amount of water. The results are given in the report.

An experience is quoted which is of peculiar interest from a different point of view. The exit from a tower type of vitriol plant was of a particularly unpleasant character, although its total acidity was consistently under one grain, stated as SO_3 per cb. ft. Complaints were made by the occupiers of a neighbouring property.

With a view to further reducing the acidity of the gases, they were passed through a coke-packed tower fed with a limited supply of water, 25—30 gals. per hour. The acidity of the gases was thus reduced to 0.2—0.3 grain, and were no longer offensive.

There has been little demand for concentrated acid, and sulphuric acid (Class II) works have been less active than formerly. At only one works was there any cause for dissatisfaction; exit acidities were there found running too high. Fan draught was not satisfactory, and this was altered with resulting improvement, though still scarcely sufficient to make good results certain. A new scrubber is, therefore, being installed. Although electrostatic precipitation has been used for some time in connexion with oleum plants and in some concentrating plants, its possibilities in connexion with the latter do not appear to be fully realised. Results have been recorded in recent years showing that 3-grain concentrator fumes can be reduced by this means consistently to 0.2 grain, all visible fume disappearing.

Eighty chemical manure works are registered, which is 16 fewer than two years ago. Superphosphate manufacture is still on a considerably reduced scale, but where it has been carried on operations have been conducted with the usual excellent condensation of acid gases, except in one instance—a works where a new mixing plant had been provided with a fan that was much too powerful. In almost all works the acidity of the escaping gases, stated as the SO_3 equivalent of hydrofluosilicic acid, has not exceeded 0.1 grain per cb. ft. The highest percentage condensation of acid gases for any one works was 99.9, the lowest 95.9.

The relatively high cost of recovery of by-product ammonium sulphate is reflected in the considerable drop in the number of sulphate of ammonia and gas-liquor works registered in recent years. In many instances the plants still exist, so that under more favourable conditions they may again be brought into operation. The prolonged coal stoppage of 1926 had a very adverse effect on the production of sulphate. The plants that operated were conducted satisfactorily, and purifiers in general were kept in good order. The amount of ammonia products (expressed as sulphate [$25\frac{1}{2}\%$ NH_3]) manufactured in England and Wales in 1926 is given in the following table:—

From liquor produced in	1926 Tons	1925 Tons	1924 Tons
Gasworks	132,477	148,945	151,161
Other works (including coke ovens, iron works, producer-gas, synthetic, etc.)	132,215	201,667	211,010
Total	264,692	350,612	362,170

NOTE.—Of the total quantity of ammonia products, the equivalent of 24,449 tons was manufactured as concentrated ammoniacal liquor; the balance of 240,243 tons consisted of other ammonia products.

The amount of tar products manufactured in England and Wales in 1926 was as follows:—

	Gas, and coke oven works Tons	Other works Tons
Tar distilled	1,157,523	44,623
Pitch produced	272,658	2,360

As the ammonia plant effluent question has reached a stage where it was considered necessary that more

complete investigation and experiment should be carried out in the works themselves, a sub-committee was appointed by the Institution of Gas Engineers to carry on such work, and full-time chemists have now taken the matter in hand. At several works the evaporation of devil liquor in waste heat flues has been adopted, together with carefully-regulated flow of the remaining effluent liquor to the place of disposal. Substitution of an acid wash, in place of the final water-scrubbing of coal gas, is also showing signs of development. Increased attention is, moreover, being directed to the beneficial effect of the more complete separation of tar at the initial stages of coal-gas purification, together with early and complete separation of the tar from any accompanying liquor.

Further work has been done in the laboratory during the year. It has been found possible to evolve a more satisfactory method of estimating the relative contamination of effluent liquors with higher tar acids, and good results have been obtained in the removal of phenol from effluent liquors by using a trough, in a waste heat flue, instead of the isolated tower previously employed. The results of the analysis of condensates obtained at two coke-oven plants are given in detail in an appendix.

The number of chlorine works registered increased from 37 to 49 during the past two years. The use of liquid chlorine in the manufacture of various products, inorganic and organic, and for other purposes, continues to extend; this is responsible for the increased number of works of this class that have been registered. In some works quite a large number of units of chlorinating plant are in constant use. Complete absorption of any excess chlorine is essential, and can be efficiently effected by means of towers fed with soda solution, the liquor being recirculated and a useful hypochlorite thus obtained. All processes in which chlorine is used need careful supervision in every detail to ensure the absence of escape.

The conditions under which the scruff from tinplating operations is treated are now such that there is little difficulty in preserving a perfectly satisfactory atmosphere in the neighbourhood of the works, the amount of hydrochloric acid emitted being negligible.

Sulphide works have all been well conducted. Complete absorption of any sulphuretted hydrogen is not accompanied by serious difficulties; proper supervision is, however, always necessary, and it is worthy of note that supervision has been good.

There was cause for remonstrance at one Venetian Red works where copperas is roasted; this is referred to in the early portion of this report. Other Venetian Red works have all operated without offence throughout the year, the acidity of the evolved gases being satisfactorily reduced before their emission to the atmosphere.

Several complaints were made as to excessive fumes from tar works. They related, however, not to anything given off in the actual distillation process, but to offensive fumes from bitumen-mixing plants. Much depends on the type of mixer used. With a mechanical mixing arrangement there is considerably less liability to evolution of fume than with air blowing. In any case, fumes can quite well be draughted by means of

a fan to a suitable condenser. Where this has been done nuisance has ceased.

Mr. J. W. Young, Chief Inspector for Scotland, in his report for 1926 to the Scottish Board of Health, states that the number of works registered was 154, in which were operated 292 scheduled processes. Visits of inspection numbered 475, plus 27 to others not on the register; 252 chemical tests of escaping gases were performed; in no case were exceeded the limits of acidity prescribed by the Act. No legal proceedings have been taken. Three works were discovered to be operating a scheduled process, "bisulphite," without previous registration.

Complaint by the burgh surveyor of a town on the River Forth was made against a chemical works of injury, by fumes emitted, to stone-work and window glass. The corrosion of stone was irregular, some pieces, save from blackening by coal smoke, being as good as when first built in; others nearby were seriously decayed. It was evident that the stone had been improperly selected. Whether or not the chemical works had contributed to the damage previously is doubtful, but through inactivity it can have had no recent share. The window glass bore on its outward surface a permanent and iridescent bloom, not to be removed by careful cleansing and polishing. This appearance has been observed throughout Scotland, even in districts free of chemical works.

Throughout 1925 there were numerous complaints in South Fife of evil odours attributed to a registered works. Foul liquids discharged from a process, not scheduled, into tidal water were suspected; it was arranged to prolong the discharging pipe, to submerge its exit at all states of tide, and by altering methods of distribution to increase dilution. Complaint has since ceased.

By the courtesy of manufacturers, the following summary of raw materials and of products is given. It bears witness to the depressed state of trade, especially in the production of iron and of its associated industries.

	1925 Tons	1926 Tons
Pyrites, blende and spent oxide burned for sulphuric acid	100,865	79,438
Phosphates and bones dissolved for fertilisers	59,270	43,130
	Salts of ammonia Tons	Tar distilled Tons
From gas works ..	18,719	132,522
.. iron works ..	816	11,114
.. coke ovens ..	2,065	6,777
.. producer gas ..	2,405	3,217
.. shale works ..	33,805	
Total 1926	58,800	53,630
In 1925 ..	78,995	188,827
		Pitch produced Tons
		25,053
		5,418
		3,067
		1,856

The ammonia is expressed as pure sulphate; 776 tons was obtained as concentrated liquor ammonia and 323 tons as ammonium chloride. About 90,000 tons of tar was dehydrated and partially distilled for road purposes.

Except at one alkali works, idle during a long period, operations were not more restricted than in 1925. Hydrochloric acid was readily taken by other industries; saltcake was chiefly exported. The average amount of hydrochloric acid discharged into the air in chimney gases was 0.04 grain per cb. ft., the extremes being 0.10 and 0.02.

In sulphuric acid and sulphuric acid (Class II) works, production fell by another fifth, the loss being due to

diminished recovery of ammonia compounds at blast furnaces and gas works. Three works were idle throughout the year. Repairs and rebuilding of chambers have been extensive; plant suffered much in the heavy gales of autumn. Additional apparatus has been erected to supply the necessary nitrous gas by oxidation of ammonia, and has worked satisfactorily. This subsidiary process has many advantages, particularly at times of starting again to manufacture acid after interruptions. One works cut out its fourth chamber, and claims to have saved nitre without reducing yield of acid.

The tendency to burn spent oxide from gas purifiers, instead of pyrites, is increasing, partly from rather lower cost and partly from the absence of arsenic. The mechanical types of kiln continue to do good work, and are more numerous. The general average acidity in each cubic foot of residual gases discharged by sulphuric acid works was 0.47 grain of sulphuric anhydride; the highest and lowest averages for any one work were 0.76 and 0.03 respectively.

Manufacture of stronger acid by the Class II process has been busily and satisfactorily maintained, with efficient condensation of acid gases before discharge. There has been no improvement in demand for ordinary concentrated acid, so that much good plant has been idle. The general average acidity of the final gases from Class II works was 0.35 grain of sulphuric anhydride.

There was again a heavy fall in production of fertilisers, and profits must have been low or absent entirely in the effort to compete with foreign imports. Plant is highly efficient, and has been kept in good order, so that condensation of corrosive gases was excellent, varying from 96.7 up to 99.7%. The average of the total acid in each cubic foot of gases escaping finally was 0.09 grain, expressed as the SO_3 equivalent of hydrofluosilicic acid.

Recovery of ammonia has been much smaller than in recent years. Less coal has been available, and that imported has contained less nitrogen. Two cases were noted of blue salt, an old trouble almost forgotten, due to cyanogen resulting from higher temperatures within gas retorts. The blame was wrongly assigned to impurities in sulphuric acid. Several works found great advantage from improving their arrangements of cooling and condensation; plants, again, have been wholly rebuilt. In three cases it was necessary to give serious warning as to neglect of saturators and purifiers. The prospects of this industry are unattractive; cost of acid and of transport of crude liquor induce many smaller works to run it wastefully to sea. Possibly direct application to agricultural soil, or an easier conversion to urea, may be the method of the future. In common with the last section, the tar works group also has suffered, and from similar causes; a consequence noted is the increased yield of naphthalene from tar distillates, and of that obstructing gas mains. Few of the older and less efficient stills now remain. There has been no complaint.

Zinc works were long idle, wanting fuel. Conditions of manufacture remain unchanged, but no complaint was received against them during the period of operation. In a few miscellaneous works there has been great activity and increased production, though not in all. Plant has been kept in good order throughout.

CORRESPONDENCE

CHEMISTRY HOUSE

SIR,—The recent announcement that the Paris municipality has contributed 500,000 francs towards the "Maison de Chimie," the Berthelot Centenary Institute, and that a number of French chemical firms have contributed sums of 200,000 francs each may perhaps serve to revive interest in "Chemistry House."

Possibly there may be in this country some distinguished living chemist, preferably as young as possible, who would devote himself to expediting the present rate of progress of the scheme and hasten its realisation by initiating at once a campaign for ensuring that the establishment of "Chemistry House" will coincide with the celebration of his centenary (or bi-centenary). "Carpe diem quam minimum credula postero."

Yours faithfully,

A. J. V. UNDERWOOD

THE "WHITE OIL" REACTION

SIR,—Most mineral oils can by the continued action of sulphuric acid be converted into a colourless and bloomless oil. The opinion is often put forward that the action consists in removing unsaturated hydrocarbons or more easily attacked hydrocarbons, and leaving originally present, more stable compounds, usually classed as paraffins. Evidence, such as is gathered in the course of commercial manufacture of these white oils, would point fairly definitely to the conclusion that the "white oil" is a by-product of reaction, i.e., was not originally present, and is generally not a paraffin, but an *iso*-paraffin.

The slight acid treatment given to lubricating oil distillates in order to prepare them for lubricating purposes generally proceeds no further than the removal of comparatively small quantities of so-called resinous substances, asphaltic bodies, traces of nitrogenous compounds, cracked hydrocarbons, and, occasionally, sulphur-containing compounds and natural petroleum acids. The soda treatment neutralises and removes the mineral acids, naphthenic acids, sulpho-acids, etc. The tars obtained are, for the most part, insoluble in water, and evidently contain a large hydrocarbon molecule. The cracked oil tars are frequently liquid and soluble, and the basic substances present form soluble acid compounds.

When this "cleaning up" treatment is over, further treatment with acid seems to proceed along other lines, namely, that of breaking up and reforming another molecule. Most lubricating oil distilled without cracking gives evidence of being a mixture of members of a definite series varying with the nature and origin of the crude. Purely cracked oils, such as the shale oils, do not give a bloomless product, and can be treated with acid, giving general liquid tars, until nothing remains except a small quantity of actual paraffin compound. The "naphthenic" oils, such as Russian, when carefully treated with acid of such strength as to attack the oil fairly readily, yet not too strong, and so give an undue amount of secondary reaction products, yield a definite percentage of white oil product of a specific gravity having a definite relation to the original specific gravity. The reaction comes to a well-defined end; the tars produced

are soluble in water, and have a high sulphuric acid content, whereas, had the action been one of separation of high specific gravity and molecular weight constituents, hydrocarbons should be found combined with comparatively small weights of sulphuric acid. By taking the yield of white oil and its specific gravity, it is easy to calculate what must have been the specific gravity of the removed oil on a supposition of a separation reaction. A few instances may be given, but in these the final yield of white oil is purposely placed under the actual commercial yield, and is probably still further under the yield obtainable by careful laboratory treatment, in which case the figures obtained would be still more striking than those given.

A Texan oil of a specific gravity of 0.935 will yield 33% of white oil of specific gravity 0.890. The removed oil should have a specific gravity of 0.957: Russian oil of a specific gravity of 0.910 will yield 50% of white oil of specific gravity 0.885; the removed oil should, therefore, have a specific gravity of 0.935: Pennsylvanian oil of specific gravity 0.865 will yield 70% of white oil of specific gravity 0.845. The removed oil, therefore, should have a specific gravity of 0.912. Numerous other examples could be given from different crudes and from different specific gravities of the same crude. Taking the Russian oils as the best known instance, it is hardly necessary to state that components with such high specific gravities have not been detected; no amount of fractional distillation will even show a slight concentration of such heavy molecules; and no method of partial solution or precipitation gives any better evidence. A Russian distillate of specific gravity of 0.89 can be distilled without decomposition, and has been fractionated and refractionated into as many as 16 different parts without giving any further evidence of other than the usual characteristics of Russian oils. Each of these fractions will yield white oil in practically the same percentage, requiring the same amount of acid, and undergoing a characteristic reduction in specific gravity. Oils from other sources behave similarly, *i.e.*, the yield, the amount of acid required, and the drop in specific gravity are characteristic of the type, and the figures are only comparatively slightly altered over a considerable range of distillates of increasing specific gravity from the same crude. It has not been forgotten that some heavy gravity distillates can be separated by solvents, such as liquid SO_2 , into a comparatively lighter and heavier fraction, but before a white oil is obtained treatment with a high percentage of sulphuric acid is still necessary.

This particular action of sulphuric acid is so well defined that it is capable of a tolerably accurate mathematical treatment. By carefully treating a distillate with successive quantities of acid of carefully-graded strength, and noticing the reduction in specific gravity, alteration of iodine value down to zero, viscosity etc., a series of figures can be obtained for each type of crude and a curve or equation can be obtained from which it is possible to take a partially-finished oil and by a few stages of acid treatment obtain figures which by reference to the equation or curve enable the original specific gravity of the oil to be calculated, as well as that of the final product.

Incidentally, one is able in many cases to identify the crude from which the oil has been prepared. This reaction, therefore, appears to be worthy of a definite name, and the term "Albreaction" suggests itself. As to the nature of the reaction, the writer has only conjecture to offer, as the compounds involved are so complex and the possibilities so great, but evidence derived from this acid reaction and the study of the products of oxidation, namely, water, various aldehydes, acids, and asphaltic bodies, point in the direction of the lower specific gravity hydrocarbons being nearest to chain compounds with probably one polymethylene ring, while those of increasing specific gravity (for any given viscosity) would appear to have more rings with or without side chains. The reactions point to a break-up of these rings and a building together of the residues into molecules on iso-paraffin lines of construction. The positions originally occupied by the rings are probably centres which are attacked when the white oil product is oxidised. Many facts are known as to the nature of the oxidation products on the natural oil, and the resemblances and differences both as to quality and quantity of the oxidation products of the derived white oil; a careful study of these promises to throw light on the structure of the lubricating hydrocarbons.

A new explanation of "formolites" is also needed.
Silvertown. WM. LEE

July, 1927

OBITUARY B. A. BURRELL

News of the death of Mr. B. A. Burrell at his home in Leeds came as a great shock to a wide circle of friends in the city and throughout Yorkshire.

Benjamin Arthur Burrell, an original member of the Society, died on July 10 at the age of 68. He was educated at the Leeds Grammar School, and received his professional training under the late Thomas Fairley, Prof. T. E. Thorpe, and George Ward, of Leeds. After a pupillage under Mr. Fairley, Borough Analyst, he acted as his assistant for eight years, during which time he taught chemistry at the Leeds Institute. He was public analyst to the City of Cork from 1883—1890, when he rejoined Mr. Fairley at Leeds, becoming later his partner, and eventually in 1919 his successor as City Analyst. He held also at the time of his death several other offices, *viz.*, Public Analyst to the North Riding of Yorkshire and to the Borough of Scarborough, Agricultural Analyst to the North and West Ridings, Consulting Chemist to the Fire Offices Committee of London, Gas Examiner for the City of Leeds and the West Riding, Water Examiner for the City of Leeds and Harrogate, and Consulting Chemist to the Yorkshire Agricultural Society. He was the author of the "Food Testing Elementary Text Book" and many papers giving the results of his analytical experience. He served on the council of the Society of Public Analysts and of the Local Section of the Institute of Chemistry, but was probably best known as the popular secretary for many years of the Yorkshire Section of the Society of Chemical Industry, of which he was chairman for the last two years.

His interests centred chiefly round his profession, and he worked indefatigably in his laboratory. Never

robust, of late years he had to contend with much illness, accelerated by an accidental fall while attending a meeting of chemists in Leeds. A severe attack of influenza last winter was followed by pneumonia, after which he never regained his normal strength.

The funeral took place on July 13 at the Woodhouse Cemetery, Leeds, when the Society was represented by Mr. H. J. Hodsman (Chairman of the Yorkshire Section), Dr. J. P. Longstaff, and many other members.

PERSONAL AND OTHER ITEMS

The Adjudicators under the Hanbury Trust have resolved to award the Hanbury Memorial Medal to Dr. T. A. Henry, F.R.S., Director of the Wellcome Chemical Research Laboratories. The medal, which will be presented on October 5, is awarded for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs.

Prof. J. F. Thorpe, F.R.S., will represent the Institute of Chemistry at the celebration of the centenary of Berthelot in Paris in October.

Sir William Bragg and Prof. R. Willstätter have been elected Honorary Fellows of the Royal Society of Edinburgh.

Sir Philip Magnus has been elected chairman of the council of the Royal Society of Arts for the year 1927-28. He succeeds Sir Thomas Holland.

On Saturday last Sir Daniel Hall, F.R.S., who recently resigned his position as Chief Scientific Advisor to the Ministry of Agriculture, was the guest of honour at a luncheon held by the East Kent Chamber of Agriculture, of which he was chairman in 1900.

Prof. D. Hanson, D.Sc., professor of metallurgy in the University of Birmingham, is on his way to New York.

Mr. I. V. L. Fergusson has been appointed a director of Evans Sons, Lescher and Webb, Ltd., Liverpool.

Mr. S. W. Woolley has retired from the editorship of the *Chemist and Druggist*.

Mr. Charles T. Bazell, Mr. Frank J. Farrell, and Mr. James Spence have resigned their positions as directors of the Branton Artificial Silk Company.

Mr. E. P. Barfield, managing director of Automatic & Electric Furnaces, Ltd., has sailed for New York to give a series of demonstrations on Wild-Barfield electric furnaces (already installed in American works), to a number of engineers and executives of the leading engineering firms in the United States.

A statue of the Comte de Chardonnet, the French chemist who invented one of the first processes for making artificial silk, is to be erected by the Academy of Science and Art at Besancon.

Alderman A. Cliff, J.P., chairman of the Association of Fire-Clay Industries, who died on April 22, aged 58, left estate of the gross value of £10,306, with net personalty £9140.

We regret to announce the death of Mr. E. Sanger-Shepherd, well-known for his work on colour photography and the development of instruments for photographic sensitometry.

Association of British Chemical Manufacturers

The annual dinner of the A.B.C.M. was held at the

Hotel Metropole on Thursday, the 14th inst. It was, as on former occasions, a most pleasant gathering. It is a standing rule at this dinner that there are no speeches; the rule was adhered to with customary strictness. A few of those present had the temerity, after assuaging the pangs, to carry on their conversation in tones which were audible, practically to all in the room. Mr. C. A. Hill, who presided, was the first to liberate his accumulated levity and eloquence; Sir Alfred Mond talked as he usually does, an utterance of good sense which seemed to escape him almost involuntarily and obviously without effort; easy speaking is probably preceded by hard thinking, but there was no outward and visible sign of the premeditation which must have been necessary, in other men, to so clear a statement of the British chemical industry and its problems. Mr. Shortt, Dr. M. O. Forster, Dr. Leonard, and Mr. Woolcock indulged in post-prandial back-chat which was extremely diverting. Many of the manufacturers enjoyed their company so much that a supplementary gathering was held in another place overlooking the river, and conversation was carried on until an early hour. This is the highest praise we can think of, that a dinner is so good that the diners refuse to separate, unwilling to retire though weary. Many, very many, men of distinction in the industry were present.

Chemical Associations and the British Industries Fair

All the leading associations in the chemical industry, including the Association of British Chemical Manufacturers, have received a letter from Mr. A. M. Samuel, Parliamentary Secretary to the Department of Overseas Trade, calling attention to the British Industries Fair, 1928, and particularly to the Chemical Section at White City.

"The Chemical and Allied Industries now provide one of the most important sections of the Fair, and the Section attracts greater attention each year from visitors," Mr. Samuel writes. "The success achieved in recent years, and particularly last year, moreover, has already induced a number of firms to consider participation for the first time in 1928. I am trying this year to make the Section thoroughly representative in all branches, and I ask for the co-operation of your Association, particularly in the direction of securing new participants."

It is pointed out that some applications for space in the London section of the Fair of 1927 had to be refused owing to lack of accommodation. For that reason arrangements have been made to provide 100,000 square feet of additional space for 1928, 1929 and 1930. Publicity literature and methods have been completely overhauled, and, with the help of His Majesty's Trade Commissioners, Commercial Diplomatic Officers and Consular Officers all over the world, an analytical examination has been made of lists of overseas buyers, the number of whom, consequently, should be even greater than the record total at the 1927 Fair.

"The Fair, which was instituted in a small way in 1915," Mr. Samuel concludes, "has grown from year to year, and has now established itself. With the continued support of the great commercial organisations, it will become increasingly valuable in helping the sale of British goods."

REVIEWS

STUDIEN ZUR GESCHICHTE DER CHEMIE. FESTGABE
E. O. VON LIPPMANN ZUM SEBZIGSTEN GEBURTSTAGE.
Edited by Julius Ruska. Pp. vi + 242. Berlin:
Julius Springer, 1927. Price 19.50 r.m.

This interesting collection of essays, edited by the famous Orientalist, Julius Ruska, of the University of Heidelberg, is presented to Prof. E. O. von Lippmann, the well-known writer on the history of chemistry, in commemoration of his seventieth birthday. The portrait of Prof. Lippmann shows that he is still youthful and active, and that we may hope to receive from him many more of those detailed and critical compendia which readers in the field of the history of chemistry know so well. No one except the recipient of the "Festgabe" could hope to give in short compass any adequate account of its contents, and hence the reviewer must limit himself to a bare mention of one or two of the articles which have interested him the most. A discussion of the points raised would fill a whole number of CHEMISTRY AND INDUSTRY.

Darmstaedter's article on Babylonian and Assyrian lapis lazuli, *aknu* (Gr. *αἰνιπερος*), obtained from Persia, and the symbol of heaven, provides an interesting example of the use of cobalt and lead in the preparation of ancient Assyrian blue glass found by Hilprecht at Nippur. Davy had long ago pointed out that cobalt was a constituent of ancient glass, and, although it is not common, we may be certain that its use was understood in the Assyrian period. Cobalt in Egyptian glasses has also been reported. Lagercrantz shows that Reitzenstein's emendation of Berthelot's reading of the Greek MS. of "Joannes the High Priest" is impossible. He himself proposes to re-write the passage *τῆς ἐν Εὐαγγίᾳ τοῦ Ἰωάννου* (which the reviewer can affirm so stands in the MS.) as *τῆς ἐν Νεφθαίᾳ οὐῶς*, and hence to make Joannes a Nabathaen! Lagercrantz is evidently not acquainted with Thompson's "Chemistry of the Ancient Assyrians," where the word *tutia* is put forward as Assyrian. The difficulty which von Lippmann (*Alchemie*, 71, and before him Kopp) felt, depending on the hypothesis that *tutia* was first used in the Arabic period, is thus removed without the need for such a far-fetched hypothesis as that of Lagercrantz. Ruska writes on the "Book of the Seventy," which, although referred to by Hoefer, was first published by Berthelot in 1906. The text, which is extraordinarily corrupt, was regarded by Berthelot as a translation of a work by Jabir ibn Hajjan, and Ruska has now examined two Arabic texts found at Cairo. These are the originals of the Book of the Seventy, and the latter is thus a translation of a genuine work of Jabir's. Ruska is of the opinion that the work is a "plant of native growth, in which chemistry is indissolubly connected with astrology on the one hand and medicine on the other," and is not an importation from Egypt. This seems doubtful, since the connexions mentioned suggest an Alexandrian environment. Zuretti gives the text of a Greek MS. in the Vatican which shows a very close relation to the text of the Latin Geber. The reviewer has suggested that a Greek text of this work probably existed.

Walden has an interesting article on the development of chemical symbols. He states that the present system, due to Berzelius, was only slowly brought into use, but an earlier work than the one he mentions (1835) is Turner's "Elements of Chemistry," in the fifth edition of which (1834) symbols and equations in the following form are used:—

Turner states in the preface that the use of symbols was introduced in the fourth edition of the book.

T. L. Davis gives an interesting account of Priestley's defence of the doctrine of phlogiston after his removal to America, and Speter has a very entertaining "Historio-chemisches Allerlei," in which, among many other things, the suggestion of a thermostat by Becher (1707) occurs.

J. R. P.

HANDBUCH DER BIOLOGISCHEN ARBEITSMETHODEN.
Edited by PROF. EMIL ABDERHALDEN. Part I, Chemische Methoden, Teil II, Heft 2. Zweite Hälfte (Lieferung 211) Die Bitterstoffe. By Wilhelm Beth; and Neuere Methoden der Isolierung und des Nachweises von Porphyrinen. By Hans Fischer. Pp. 146. Berlin and Vienna: Urban & Schwarzenberg, 1926. Price 7.20 m

The "bitter principles," or, as they are more usually called in this country, the "neutral principles," form a kind of dust-bin into which are thrown all the nondescript constituents of plants that cannot be assigned to the pigments, glucosides, tannins, resins, gums, phytosterols, or any other of the large classes of non-nitrogenous substances now recognised as common constituents of plants. From time to time a chemist takes something out of the dust-bin, determines its constitution, and so assigns it to its appropriate group. The bin is, however, constantly replenished by the side-issues added to it by the chemist, primarily interested in, say, alkaloids or pigments. The value of a compilation of this kind is therefore to call the attention of chemists to the existence of the dust-bin, in the hope that some of them may be induced to lend a hand in emptying it. Few of these substances are commercial articles, but the raw materials yielding them are often easily obtained, and the substances not difficult to isolate, so teachers looking for subjects for research students might well devote some attention to them, and they will find Dr. Beth's compilation a useful guide in making a selection.

H. Fischer's contribution to this section of Abderhalden's great book concerns a subject, the porphyrins derived from blood and leaf pigments, to the chemistry of which he has made voluminous and interesting contributions. In this country we have been content to admire, and not to participate in these ingenious researches, and those chemists interested in the borderland between biology and chemistry will be glad to have this admirably clear account of this work.

T. A. HENRY

PARLIAMENTARY NEWS

Revenue from Safeguarding Duties

In reply to Mr. Harris, the Financial Secretary to the Treasury (Mr. Ronald McNeill) said that during 1926-27 the net revenue derived from the safeguarding duties on mantles for incandescent lighting was £11,031, on packing or wrapping paper £494,851, and on key industry goods £505,323. The total receipts from safeguarding duties amounted to £1,919,958.—July 18.

Pollution of Rivers

In the House of Lords, Lord Mildmay said that the voluntary Committee on River Pollution had practically exhausted its possibilities. Many streams were still being fouled through ignorance or negligence, and it was essential to create some central, inter-departmental authority for the whole of our rivers, within the limits of the need for national economy, but adequate to the importance of the task. Lord Balfour fully agreed with the necessity of the work, but was equally impressed with its difficulty. It was often necessary to choose between the purity of a river and the ruin of a factory or a new industry. For example, the effluents from low-temperature carbonisation, coke ovens, beet sugar, and artificial silk were extremely noxious. The solution was probably research into the proper method of rendering them innocuous, and the Government had already set up a special Committee of experts to co-ordinate, select, and extend the world-wide experiments being carried on in this direction. The Government had also decided to set up a special inter-departmental Advisory Committee, under Sir Horace Monro, which should explore the possibilities of more harmonious and connected control of rivers, and continue the systematic attempts to deal with certain causes of pollution, such as sewerage, for which loans totalling £5,000,000 had been made in a single year.—July 18

S. Staffordshire Mond Gas Company's Bill

The Board of Trade has offered strong support to new proposals for the development of the British chemical industry contained in a Bill promoted by the South Staffordshire Mond Gas Co. The Bill, having been through all stages of the other House, was held up by the Unopposed Bills Committee of the House of Commons recently, because of the precedent it involved, which the Committee could not see its way to establish on its own responsibility. The Bill seeks to extend the company's powers so that it may manufacture paints, preservatives, disinfectants, antiseptics, medicines for human beings and animals, and any other chemical compound or compounds of a like description. When the matter came again before the Unopposed Bills Committee in the House of Commons on July 15, a proviso was added restricting the proposed developments and experiments to the use of residuals already produced by the company or in conjunction or association with such residuals. Another clause provides that the company may manufacture and store on its lands, and may supply, sell and deal in oxygen, hydrogen, nitrogen, carbon dioxide, carbon monoxide, methane, ethylene, acetylene, sulphuric acid, hydrochloric acid, nitric acid, and acetic acid. The company was already

making a large amount of producer gas, which was the starting point for the by-products it now wanted to further develop.
